

The University of Toronto
Chemical Library

Presented
to

The University of Toronto Library
by

William Lash Miller, B.A., Ph.D., C.B.E.
Professor Emeritus of Physical Chemistry

for

A Departmental Library to be under

the control of the Professor of

Chemistry according to the conditions

set out in a letter from the Librarian
of the University dated, March 21st

1938.

The Society of Chemical Industry.

LIST OF PAPERS COMMUNICATED TO THE SOCIETY AND PUBLISHED IN THE JOURNAL IN 1909.

N.B.—The words within () indicate the Journal in which the Paper appears and the Section before which it was read.

	PAGE		PAGE
Alexander, J. Colloid chemistry and some of its technical aspects. (March 31, New York)	280	Fraps, G. S. Determination of cottonseed hulls in cottonseed meal. (June 15, New York)	590
Allan, J. See Radcliffe, L. G.	227	Gardner, W. M. Some chemical aspects of the textile industries. (Abstract.) (Jan. 15, Yorkshire)	13
Anderson, W. C. The factors that constitute value in teas. (March 31, Scottish)	285	Goldsbrough, H. A. See Schidrowitz, P.	3
Baker, J. L., and H. F. E. Hulton. Behaviour of wheaten flour towards bakers' and brewers' yeast. (July 31)	778	Green, A. G. The quinonoid salts of the phthaleins, and the cause of colour in the triphenyl-methane series. (June 30, London)	638
Toxicity of flours towards <i>Saccharomyces cerevisiae</i> . (July 31)	781	Griffin, M. L. A mathematical view of sampling, with reference to the degree of accuracy to be obtained. (Feb. 27, New England) ..	192
Beadle, C., and H. P. Stevens. By-products of cottonseed and their utilisation (Oct. 15, Liverpool)	1015	Hake, C. N., and M. Bell. Action of sulphuric and nitric acids in the nitration of cellulose. (May 15, London).....	457, 823
Machine for the mechanical testing of india-rubber. (Nov. 15, London)	1111	Harbord, F. W. Manufacture of iron and steel in relation to other industries. (Aug. 31, Birmingham)	867
Occurrence of mouldiness in paper pulp. (Abstract.) (Oct. 15, Liverpool).....	1015	Heathcote, H. L. The university training of industrial chemists. (Abstract.) (Feb. 27, Birmingham)	171
Bell, M. See Hake, C. N.	457, 823	Hendrick, J. The lime in basic slag. (July 31, Scottish)	775
Bennett, H. G. Commercial control of tannery lime liquors. (March 31, Yorkshire).....	292	Hibbert, E. Volumetric estimation of copper and chromium, and of copper, chromium, and iron in admixture. (Feb. 27, Manchester)	190
Estimation of nitrogen in organic substances. Determination of hide-substance in leathers and of dissolved hide-substance in soak liquors and lime liquors. (March 31, Yorkshire)	291	Volumetric method for the estimation of titanium, and of titanium and iron in presence of each other. (Feb. 27, Manchester)	189
Briggs, J. F. Cellulose as a polysaccharide. (April 15, London)	340	Higgins, S. H. Relation between the absorption of moisture and of dyestuffs by textile fibres. (Feb. 27, Manchester)	188
Carulla, F. J. R. Tests for the action of chlorides on cast iron. (May 31, Nottingham)	508	Hiorns, A. H., and S. Lamb. Influence of small quantities of arsenic and antimony on copper. (May 15, Birmingham)	451
Caven, R. M. Detection and estimation of chloride in presence of bromide, and estimation of chloride, bromide, and iodide in mixed solution. (May 31, Nottingham)	505	Hirst, S. See Procter, H. R.	293, 294
Chick, O. See Howard, B. F.	53	Holley, C. D. Manufacture and properties of mild process white lead. (April 30, New York)	403
Coste, J. H. Technical gas calorimetry. (Dec. 15, London).....	1231	Howard, B. F., and O. Chick. Cinchonamine and certain other rare alkaloids. (Jan. 30, London)	53
Cowper-Coles, S. O. Vapour-galvanising. (April 30, London).....	399	Hübner, J. Effect of addition of salt to the caustic soda lye used in mercerising. (March 15, Manchester)	228
Dains, H. H. The Indian magnesite industry. (May 31, London).....	503	and F. Teltscher. The action of caustic soda lye on cotton. (June 30, Manchester)	641
Davidson, W. B. Modern developments of the gas industry. (Dec. 31, Birmingham)	1283	Rhodes, L. S. Sublimed white lead. (April 30, New York)	405
Davies, S. H., and B. G. McLellan. Rapid determination of carbon dioxide in the atmosphere. (March 15, Yorkshire).....	232	Erratum	464
Donnan, F. G. The university training of technical chemists. (March 31, Liverpool)	275	Hulton, H. F. E. See Baker, J. L.	778, 781
Donovan, W. See MacLaurin, J. S.	827	Humphreys, T. C. See Price, T. S.	117
Dreaper, W. P. The artificial silk industry. (Dec. 31, London)	1297	Huntly, G. N. Sulphur as a cause of corrosion in steel. (April 15, London)	339
and A. Wilson. Reactions between fibres and dyes. (Jan. 30, London).....	57	Jorissen, W. P., and J. Ratten. Naphthalene picrate, and the determination of naphthalene. (Nov. 30, London).....	1179
Duncan, R. K. Industrial fellowships. (July 15, London).....	684		
Emslie, B. L. The Stassfurt potash salts. (April 30, Canadian).....	393		
Ewan, T. Estimation of sulphide in alkali cyanide. (Jan. 15, Scottish)	10		

	PAGE		PAGE
Klipstein, E. C. Influence of chemistry on the utilisation of quebracho. (April 30, New York)	408	Schryver, S. B., and R. Lessing. Physico-chemical method for comparing the antiseptic value of disinfectants. (Jan. 30, London)	60
Kulmke, E. A. J. A new steam-meter. (June 30, London)	633	Shutt, F. T. Influence of environment on the composition of wheat. (April 15, Canadian)	336
Lamb, S. See Hiorns, A. H.	451	Smith, W. Boghead cannel or "Torbanic Hill mineral." (Abstract.) (April 30, London)	398
Law, D. J. See Procter, H. R.	297	Snell, J. F. Chemistry in its relation to food. (Jan. 30, Canadian)	49
Lessing, R. See Schryver, S. B.	60	Southcombe, J. E. Analysis of oil from the seeds of <i>Symphonia globulifera</i> . (May 31, Liverpool)	499
Lester, J. H. Partial mercerisation of cotton cloth. (March 15, Manchester)	230	Composition of shea butter. (May 31, Liverpool)	499
Lewis, E. A. The chemist's relation to the copper and brass industries. (June 15, Birmingham)	584	Stansbie, J. H. Influence of small quantities of elements in copper on its reactions with nitric acid. (March 31, Birmingham) ...	268
Lewkowitsch, J. A new refractometer. (July 31, London)	773	Stead, J. C. Manufacture of artificial stone from sand and lime. (Dec. 31, London)	1295
Lovibond, J. W. Some requirements of a colour standard. (May 31, London)	500	Stevens, H. P. See Beadle, C.	1015, 1015, 1111
Mackey, W. McD., and J. Miller. The cost of treating trade effluents. (Nov. 30, Yorkshire)	1183	Stewart, S. Detection of dammar resin in kanri resin. (April 15, Scottish)	348
MacLaurin, J. S., and W. Donovan. Rapid and accurate method for estimating iron in iron ores. (Aug. 16, Sydney)	827	Tatlock, R. R., and R. T. Thomson. The value of the Polenske test in the analysis of oils and fats. (Jan. 30, Scottish)	69
McLellan, B. G. See Davies, S. H.	232	Taylor, J. M. Rapid method of determining zinc in presence of iron. (Dec. 31, Liverpool) ..	1294
May, O. B. Utilisation of magnesia in the preparation of oils in powder form. (Aug. 16, New York)	826	Teltscher, F. See Hübner, J.	641
Miller, E. V. The circulation of heated liquids. (Feb. 15, Sydney)	125	Thompson, G. W. Dutch process white lead. (April 30, New York)	406
Miller, J. See Mackey, W. McD.	1183	Thompson, J. T. The Fifth Report of the Royal Commission on Sewage Disposal. (Jan. 30, Yorkshire)	72
Moore, R. W. The chemical schedule and the tariff. (Aug. 16, New York)	825	Thomson, R. T. See Tatlock, R. R.	69
Nathan, F. L. Guncofton and its manufacture. (Feb. 27, London)	177	Threlfall, R. Spontaneous heating of coal, particularly during shipment. (July 31, Birmingham)	759
Pentecost, S. J. Recent progress in the textile industries. (Nov. 30, Nottingham)	1180	Traquair, J. Manufacture and properties of some starch esters. (March 31, Scottish) ...	288
Perkin, A. G. Some indigo products from Northern Nigeria. (April 15, Yorkshire)	353	Trobridge, F. G. The bases contained in the tar from Otto-Hilgensteck coke ovens. (March 15, Newcastle)	230
Perry, J. P. H. Reinforced concrete industrial buildings. (April 30, New York)	411	Trotman, S. R. A new chromogenic organism. (Dec. 15, Nottingham)	1238
Porter, H. The movement of gases in vitriol chambers. (April 15, Liverpool)	338	The growth of micro-organisms on cotton. (Dec. 15, Nottingham)	1237
Porter, C. J. Chemical changes in Portland cement concrete, and the action of sea water thereon. (Jan. 15, Newcastle)	6	See Wood, J. T.	1304
Price, T. S., and T. C. Humphreys. Apparatus used in rapid electro-analysis. Analysis of brass. (Feb. 15, Birmingham)	117	Vorisek, A. Detection of methyl alcohol in ethyl alcohol. (Aug. 16, New York)	823
Procter, H. R. The accuracy of the method of determination of the International Association of Leather Trades Chemists. (April 15, Yorkshire)	351	Wagner, T. B. The American industry of corn products. (April 15, New York)	343
and S. Hirst. Detection of sulphite-cellulose liquors in tanning extracts. (March 31, Yorkshire)	293	Wiley, H. W. The use of preservatives in foods. (Abstract.) (Jan. 30, New York)	67
Use of the Loewenthal method in the control of tannery liquors. (March 31, Yorkshire) ..	294	Wilkie, J. M. Colorimetric determination of lead in presence of iron. Preparation of lead-free reagents by co-precipitation with ferric hydroxide. (June 30, London)	636
and D. J. Law. Diffusion of chromium, iron, and aluminium salts through gelatine jelly. (March 31, Yorkshire)	297	Volumetric determination of phosphoric acid and mono-alkali and di-alkali phosphates. (Jan. 30, Nottingham)	68
Radcliffe, L. G. Examination of carbon tetrachloride. (March 15, Manchester)	229	Discussion	464
and J. Allan. The constants of Jasmine flower wax. (March 15, Manchester)	227	Wilson, A. See Dreaper, W. P.	57
Roderer, H. S. Lithopone. (April 30, New York) ..	403	Wood, J. T., and S. R. Trotman. The amount of skin substance dissolved in fellmongers' collecting limes. (Dec. 31, Nottingham) ..	1304
Ruttan, R. F. Ethyl alcohol from sawdust and other wood waste. (Dec. 31, Canadian) ..	1290	Wright, A. M. Methods of chemical control in the New Zealand Meat Freezing Works. (Feb. 15, Sydney)	124
Rutten, J. See Jorissen, W. P.	1179	The absorption of moisture from the atmosphere by wools. (Oct. 15, Sydney)	1020
Schidrowitz, P. The structure of crude indiarubber. (Jan. 15, London)	6		
and H. A. Goldsbrough. Viscosity of indiarubber solutions, with special reference to its bearing on the strength or "nerve" of crude rubber. (Jan. 15, London) ..	3		

Journal of the Society of Chemical Industry.

VOL. XXVIII.—1909.

INDEX OF AUTHORS' NAMES.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a patent.

Where the letter *r* follows the number of a page, it indicates, in the case of a patent, that a reference only to a previous patent appears on that page; in the case of articles other than patents, the title only of the article will be found on such pages.

The titles of new books are given within quotation marks.

	PAGE		PAGE
A		Act.-Ges. f. Anilinfabr.— <i>cont.</i>	
Abderhalden, E. "Biochemischen Arbeitsmethoden; Hand- buch der —"	859	Sulphide dyestuffs; Manufacture of — (P) 19 <i>r</i> , 305, 651 <i>r</i> , 1082	
Proteins; Partial hydrolysis of some	323	Sulphide dyestuffs soluble in water; Manufacture of — (P)	650, 651 <i>r</i> , 833 <i>r</i>
Silk; Composition and structure of various species of —	240	Thioanilinesulphonic acids; Manufacture of — (P) ..	697
and L. Befrend. Silk; Mono-amino acids of Canton — ..	518	Act.-Ges. f. Buntpapier- u. Leimfabr. and H. Metzger. Paper; Marbling — (P)	1163 <i>r</i>
and G. A. Brossa. Silk; Mono-amino acids from Niät ngo tsâm (China)	1083	Act.-Ges. f. Kohlendestillation. Ammonia from distillation gases; Recovery of — (P)	516, 693 <i>r</i>
and H. R. Dean. Silk; Formation of —	518	Coke oven; Horizontal regenerative — with hori- zontal flues (P)	237, 1080 <i>r</i>
and A. Rilliet. Silk; Mono-amino acids of New Chwaog —	240	Coke quenching apparatus (P)	81
and A. Schittenhelm. Peptolytic ferments; Detection of —	1057	Act.-Ges. f. Maschinenpapierfabr. See Opfermann, E.	1270
and W. Spack. Silk; Mono-amino acids from Indian tussah —	1083	Act.-Maschinenbau-Anst. vorm. Venueth und Ellenberger. Fat from bodies of animals; Separating, sterilising, and clarifying — (P)	250
and W. Weichardt. Silk-worm moth; Mono-amino acids of the body of the —	518	Glue solutions; Manufacture of — free from fat (P) ..	897
and Worms. Silk; Mono-amino acids from the gum of Canton —	1083	Adams, W. H. See Carroll, C. G.	26
and others. Silk; Hydrolysis of — by strong acids	978	Adler, E. See Sabersky, E.	429
Silks; Mono-amino acids from Shantung tussah and Bengal —	978	Adler, O. Sugars and benzidine; Compounds of —, and isolation of levulose	667
Abell, J. H. See Kershaw, C. R.	422	Adler, W. Arsinosalicylic acid; Preparation of — (P)	1326
Abraham, K. Diffusion; Continuous — (P)	1157	α -Naphtholarsinic acid; Preparation of — (P)	220
Abresch, E. See Schneider, G. C.	1043, 1256	Administration der Minen von Buchsweiler. Starch; Manufacture of soluble — (P)	1217 <i>r</i>
Abt, G. Leather manufacture; Chemical and biological researches on —	252 <i>r</i>	See Paira, A.	950
Achl, L. See Boehringer, C. F. und Söhne	675 <i>r</i>	Adolph, G., and others. Carbon electrodes for electro- analysis; Making durable — (P)	1092 <i>r</i>
Acheson, E. G. Deflocculating non-metallic amorphous bodies (P)	1035	Aeby, J. Calcium cyanamide	252
Non-aqueous mixtures; Preparation of — (P)	236 <i>r</i>	Agno, I. See Nasioi, R.	1247
and International Acheson Graphite Co. Graphite; Manu- facture of — (P)	708 <i>r</i>	Agnew, J. W. See Henderson, G. G.	258
Acker, C. E. Electrolytic process of producing compounds (P) Nitrogen compounds; Electrolytic production of — (P) ..	371	Agulhon, H. Ferment action; Influence of boric acid on —	668
Acker, J. B. Gas furnace; Regenerative — (P)	647	Ahlors, L. Pine oil, pine tar oil, and wood tar oil; Purifica- tion of — (P)	151
Ackermann, W. Boric acid glass (flux); Manufacture of soluble — (P)	1034, 1317 <i>r</i>	Ahlors, E., and H. Helin. Sulphite wood pulp; Resin con- tent of —, and its effect on paper-making.	438
Acme Cement Plaster Co. See Jones, T.	426	Ahrens, O. See Schmitt, P. A.	437 <i>r</i>
Act.-Ges. f. Anilinfabr. <i>p</i> -Aminoophenol, its homologues and derivatives; Manufacture of — (P)	698 <i>r</i>	Ahrle, H. Caro's acid; Synthesis and formula of —	363
<i>p</i> -Aminophenylarsinic acid; Mercury salt of — (P) ..	1273	Aigner, F. See Dynamit A.-G. vorm. Nobel und Co.	329 <i>r</i>
Aniline and its homologues and derivatives; Manufacture of — (P)	698 <i>r</i>	Akerlund, G. Gas producers (P)	787
Azo dyestuffs (P) .. 19 <i>r</i> , 596 <i>r</i> , 697, 790, 1082, 1082, 1120, 1121 <i>r</i> , 1190, 1310, 1310 <i>r</i>		Aktiebolaget Baltic Separator, and J. V. M. Risberg. Butter; Manufacture of — (P)	157 <i>r</i>
Azo dyestuffs from <i>p</i> -aminophenylarsinic acid (P)	960	Aktiebolaget Elektrometall. Furnace; Electric — for treat- ing ores (P)	1047, 1145 <i>r</i>
Azo dyestuffs; <i>o</i> -Hydroxymono — (P)	18 <i>r</i>	Iron, steel, and other metals; Electric production of —, and furnaces therefor (P)	944
Azo dyestuffs for lakes (P)	238, 977, 1030 <i>r</i>	Aktiebolaget Separator. Beet juice; Defecation of crude — (P)	806
Camphene; Manufacture of — (P)	220, 392, 626 <i>r</i>	Centrifugal machine (P)	236 <i>r</i>
Libromonomethylglycine- <i>o</i> -carboxylic acid (P)	1327	Separating solids from liquids; Centrifugal apparatus for — (P)	77, 646 <i>r</i>
Dyestuff for hair (P)	698 <i>r</i>	Separators; Centrifugal — (P)	1100
Phenoxazine derivatives; Preparation of — (P)	696 <i>r</i>	Strainer; Continuous — (P)	356, 1308 <i>r</i>
<i>p</i> -Phenylenediamine; Manufacture of — (P)	583, 698 <i>r</i>	and A. J. Ericsson. Drying; Centrifugal machine for — (P)	15 <i>r</i>
<i>p</i> -Phenylenediamine monosulphonic acid; Manufacture of — (P)	86	Aktiebolaget Swedish Nitric Syndicate. See under Swedish. Alba Manufacturing Co. See Moffatt, A.	318

	AGE	PAGE
Albahary, J. M. Cocoa and chocolate; Oxalic acid in —	738	26
Albert, C. A. J. Oil; Purification of waste — (P)	944	1141
Albert, E. Printing plates; Production of — (P)	1063	486
Albert, R. Soils; Acidity of —	432	800
Alberti, A. Potassium salts in residual liquors from tartaric acid manufacture; Extraction of — (P)	1313	712
Alberti, R. Slags and burnt pyrites containing iron and barium; Treatment of — (P)	1219	1319r
Albon, I., and W. R. Parker. Fire-bricks; Manufacture of — (P)	244	1239
Albrecht, M., and E. Erdöl und seine Produkte; Das —	860	247
Albright, G. S. University training of industrial chemists	172	805
Alcock, F. H. Antimony sulphuration	913	651
Copper and brass industries; Chemists' relation to the —. Discussion	589	1238r
Alders, H., and A. Stähler. Electro-analytical precipitations and separations	917	285
Lead phosphates	834	802
Aldridge, W. H. See McNab, A. J.	149	1008
Alfeld, E. Halogens; Determination of — gravimetrically by silver nitrate	163	1217
Alexander, F. W. Disinfectant; Electrolytic — and others. Unstable solutions (bleaching liquors, &c.); Treatment of — (P)	139	107
Alexander, J. Colloid chemistry and some of its technical aspects	280	1138
Alexandrow, W. Sulphites, sulphates, and thiosulphates; Detection of —	138	1033
All-Cohen, E. S., and others. Electric cables; Manufacture of — (P)	715	493
Allaire, H. See Desvaux, L.	1001r	1154
Allan, F. M. Clinker for making Portland cement; Manufacture of — (P)	245r	949
Allan, J. Jasmine flower wax. Discussion	227	798
and J. Richmond. Melting bitumen material, pitch, &c.; Boilers for — (P)	974	221, 222
See Radcliffe, L. G.	227	1091r
Allen, G. W. J. Beer and other fermented liquors; Manufacture of — (P)	1217	1091r
Water and other liquids; Means for filtering and aerating — (P)	540	1323r
Allen, W. H. Metal salts; Formation of — (P)	204	901
Allendorf, A. and W., and J. Rudeloff. Explosive containing trinitrotoluene for shells, torpedoes, etc. (P)	43r	1243
Allers, R. See Fränkel, S.	671	211
Allgem. Elektrizitäts Ges. Nitric oxide; Concentration of — (P)	967	615
Pumps; Centrifugal — (P)	15	980
Allot, H., and G. Gimel. Cider apples; Washing —	1099	317
Allott, J. B., and A. M. Philips. Centrifugal machines (P)	1077	1061
Raising sewage or other liquid by air pressure (P)	489	1143r
Allsop, T., and others. Dyeing apparatus (P)	519	315r
Alsbach, C. L. Guaiacum reaction; The —	41	1045r
Alsop, W. K. Acid-determination in tannery liquors; Gelatin-hematin method of —	721, 844	688
Chestnut wood; Analysis of —	484	514r
Altolaguirre, M., and J. Zubillaga. Sugar; Production of — (P)	321	839
Altshul, J. See Act.-Ges. f. Anilinfabr.	1273	753
Aluminium Co. of America and others. Alumina; Manufacture of — (P)	600, 1249	980
Alumina; Recovery of soda in manufacture of — (P)	1249	1045r
Alumina; Removal of silica in manufacture of — (P)	1249	688
Alumina and its alloys; Making castings of — (P)	428	514r
Alvares, J. Iron or chromium; Passivity of — in acid solution	371	839
Alvarez, P. y. Vanadium; Rapid determination of —	1202	104
Alverstone, Lord. Chemistry and the law	921	436r
Alvord, E. H. Filter-press; Power — (P)	357r, 502r	331
Alway, F. J., and R. M. Pinckney. Soil nitrogen of Nebraska prairies; Relation of native leguminous plants to —	1261	1124
Amberg, R. Electric steel furnaces; Characteristics of — in relation to deoxidation and desulphurisation	208	1323
Amberger, C. See Paul, C.	156, 157	300r
Ambronn, H. Cement; Recrystallisation and formation of colloids during the setting of —	306	474r
American Air Liquefying Co. See Place, J. P.	522r, 939, 957	753
American BacterIALIZED Fertilizer Co. Fertilisers (P)	212r	788
American Circular Loom Co. Electroplating process and apparatus for hollow articles (P)	372r	1321
American Cyanamide Co. See Peacock, S.	1251	800
American Dynamite Co. See Briggs, F. J.	1168	784
American Electric Furnace Co. See Hay, J. A.	1045	36
American Iron and Steel Alloys Co. See Carpenter, F. R.	794	83
American Mahogany Co. See Hall, W. A.	303, 796, 1037, 1250	753
American Phosphorus Co. See Landis, G. C.	999	582
American Reduction Co. See Rendall, G. F.	207, 479, 1043, 1205	654
American Reduction and Refining Co. See Dawson, O. B.	1142	107
American Steel and Iron Co. See Carpenter, F. R.	794	107
American Steel and Wire Co. See Huxley, H. M.	1141	107
American Sugar Refining Co. See Pool, J. F.	486	107
American Electro-Hermetic Co. See Dion, L.	800	107
Ames, W. V. B. Cement ingredient (P)	712	107
Andes, J. H., and Amies Asphalt Co. Mastic for paving (P)	984, 1319r	107
Ammon, P. Paper pulp in French West Africa	1239	107
Ammonia Cyanide Eng. Co. See Mosher, D.	247	107
Andersen, A. C. Molasses; Determination of sucrose in —	805	107
Andersen, N. See Pelet-Jolivet, L.	651	107
Anderson, W. C. Tea manufacture — the withering process	1238r	107
Teas; Factors that constitute value in —	285	107
Andés, L. E. Acaroid resin; Red —	802	107
Andorff, C. Gases; Registering apparatus for analysis of — (P)	1008	107
Andonard, A. and P. Wines of Loire-Inférieure; Free tartaric acid in —	1217	107
Andrejew, P. Petroleum from Tschimion; Analysis of —	107	107
Andrew, J. H. See Edwards, C. A.	1138	107
Andrews, L. W. Potassium iodide; Absence of iodate from commercial —	1033	107
and H. V. Farr. Arsenic; Volumetric determination of small quantities of —	493	107
Andrik, K., and J. Urban. Beets of high potash- and low soda-content	1154	107
and others. The Hyros-Rak diffusion process in 1908-9	949	107

Dyeing; Process of — (P)	471, 792, 936r, 1122r	Bihrend, L. See Abderhalden, E.	518
Dyeings on vegetable fibres; Producing yellow — (P)	1195	Bihrend, S. K. Filter press (P)	691
Dyestuffs; Fixation of — on fibre (P)	653r	Behrens, J. G. Carbon dioxide; Separation of — from gaseous mixtures (P)	938
Dyestuffs; Manufacture of basic — (P)	469, 470r, 595, 933r, 933r, 1030r	Beiersdorf, P., and Co. Soaps containing peroxides; Manufacture of — (P)	30r, 532r
Flavopurpurin; Preparation of — (P)	85, 933r	Beindl, C. Hydrocyanic acid and cyanogen compounds; Preparation of — (P)	1314
Gallocyanine dyestuffs; Manufacture of — (P)	595, 698r, 1029, 1121r	Beirmaert, H. Smoke; Purifying and rendering innocuous — (P)	302
Gallocyaninesulphonic acids; Manufacture of — (P)	977	Belani, E. Papermaking; Mineral loading materials for —	105
Hydro-aromatic alcohols or thymol and salicylic esters; Preparation of mixed carbonates of — (P)	259	Belart, H., and Digit Disinfectant Co. Compounds for internal use (P)	1325
Hydrosulphites; Manufacture of alkali — (P)	90, 90r, 310r, 600r, 708, 1087r	Bell, M. See Hake, C. N.	457, 823
Indigo compounds; Manufacture of — (P)	18, 304, 305r, 1191r	Bell Bros., Ltd., and W. L. Johnson. Furnaces (P)	1239
Mercaptans of the anthraquinone series; Manufacture of — (P)	469	Bellet, F. Ultramarines; Manufacture of — (P)	1212r
1-8-Naphthylendiamine; Manufacture of condensation products from — (P)	470r	Belloe, G. Metals; Emission of gas by heated —	1203
Naphthylpyrazolonesulphonic acid (P)	198r	Beltzer, F. J. G. Bleaching process; The electrolytic —	86
Nitro-1-8-naphthylsultamsulphonic acid and 2-4-dinitro-1-8-naphthylsultam; Preparation of (P)	650	Hypochlorites; Preparation of alkali —	86
Organic liquids; Apparatus for removing water from — (P)	1005	Dyeing hair and fur —	934
Paint and varnish; Antifouling — (P)	98, 98r	Benberg, J. P., A.-G. Calendering machines (P)	653
Preservative compositions (P)	540r	Benda, L. See Meister, Lucius, und Brünig	343r
Pharmaceutical compounds (P)	854, 1223r	Bendixsohn, K. See Fischer, F.	149
Pharmaceutical compounds from chaulmoogra oil (P)	1273	Bendle, S., and others. Wine or other alcoholic liquid; Nourishing — (P)	1058r
Phthalimino-acidylcatechol ethers; Preparation of — (P)	675	Benedicks, C. Pearlite; New structural form of —	1040
Printing (P)	363r	Benedict, S. R. Reducing sugars; Reagent for detecting —	385
Printing with sulphide dyestuffs (P)	137r	Beneker, J. C. Wire and metal cleaning bath (P)	428
Printing on textile fibres (P)	598, 936r	and Meaker Co. Tin or allied metals; Electrolytically coating with — (P)	662
Printing with tri- and tetra-bromindigo (P)	882, 936r	Benelli, T. See Paterno, E.	1168
Purine derivatives; Manufacture of — (P)	160, 854r	Bénier, L. Gas producer (P)	788
Pyrimidine derivatives; Preparation of — (P)	328	Benkő, S. Galvanic batteries (P)	1257
Resin-like product (P)	720r	Benner, H. W. Water-gas and coal-gas; Apparatus for making — (P)	512
Santalol ethers and santalyl halides; Preparation of — (P)	108r, 161r, 1006r	Bennett, A. H. Lemon oil; Determination of aldehydes in —	159
Soaps containing mercury compounds; Manufacture of — (P)	1211	Bennett, H. G. Leather; Determination of glucose in —	947
Starch; Soluble — (P)	1322r	" Leather; Manufacture of —	1106
Sulphide dyestuffs; Manufacture of — (P)	86r, 1190	Nitrogen; Determination of — in organic substances, and determination of hide substance in leather and dissolved hide-substance in lime and soak liquors	291
Sulphide dyestuffs; Manufacture of yellow- and orange-dyeing — (P)	517	Tannery lime liquors; Control of —	292
Thioindigo dyestuffs; Manufacture of — (P)	361r	Tanning extracts; Detection of sulphite cellulose liquors in —. Discussion	294
Xanthine and guanine derivatives substituted in the 8-position (P)	1167	Tanning sole leather with mimesa bark. Discussion	76
Bayliss, T. R., and others. Metallic plating, coating, or fouling; Removing — (P)	149r	Bennett, W. E. Gold amalgam; Apparatus for distilling mercury from — (P)	1204
Bayliss, W. M. Congo Red and other dyestuffs; Osmotic pressure of —	790	Bennie, P. M. See Brindley, G. F.	1087
Bayne, E. D. C., and L. A. Subers. Thread; Coating — (P)	979	See General Electric Co.	657
Bazin, C. M. D. Hydrocarbons with acid functions (from petroleum); Use of — as substitutes for fatty acids, oils, and soaps (P)	991	Bennitt, F. See Dwight, A. S.	427, 428r
Beadle, C. Fibres and dyestuffs; Reactions between —. Discussion	60	Benoit, A. See Torrini, E.	100, 1150r
and H. P. Stevens. Borneo tallow; Nuts yielding —. Cotton-seed; By-products of — and their utilisation. Indianrubber; Machine for mechanical testing of —. Paper pulp; Mouldiness in —	1146, 1015, 1111, 1015	Bentham, J. A. See Kelly, W. F. C.	492r
Beaulieu, L. Skins; Machine for carroting — (P)	882	Bentley, W. H. See Clayton Aniline Co.	259
Béchamp, Thioindigo; Derivatives of —	790	Berdel, E. Marly clay as fluxing material for easily fired bodies. Porcelain or china-ware of low fusing grade; Manufacture of — (P)	1128, 310, 475r
Béchevot, A. Gas generators (P)	1027, 1027r	Berendes, R. See Bayer, F., und Co.	675r
Bechhold, H. Disinfectants; Testing —	1162	Beretta, A. See Oddo, B.	918
and Voss. Sewage sludge; Recovery of grease from —	1000	Bereza, St. See Standinger, H.	107
		Berg, A. Elaterin	745
		Berg, R. Carnauba wax; Saponification of —	991
		Bergel, S. Blood; Production of a therapeutic agent from — (P)	1062

Schmidt, E. See Ruskowski, B.	1030	Schultz, G., and J. Führer. <i>n</i> -Propylbenzene in coal tar	1188
Schmidt, F. L. Nitric acid; Manufacture of — (P)	937	and E. Hartogh. <i>n</i> -Decane in coal tar	1188
Schmidt, M. Earthenware glazes; Leadless —	600	and E. Herzfeld. Pseudocumene in coal tar	1188
Schmidt, M. R., and H. C. Jones. Solvents containing glycerol; Conductivity and viscosity of mixed —	856	and O. Löw. <i>o</i> -Nitro- <i>p</i> -cresol; Behaviour of — towards sulphuric acid	303
Schmidt, P. G. Gas producer (P)	131, 196	and A. Perl. Naphthalene; Constituents of solvent —	1188
Schmiedt, E. Gas purifying apparatus (P)	1027	and A. Sander. Coal tar; Ethylbenzene and other constituents of — (P)	877
Schmitt, P. A., and O. Ahrens. Albumin; Drying — (P)	437r	Schultze, C. W., and Clarine Co. Water; Compound for purifying — (P)	1220r
Schmitz, H. Igniting compositions; Manufacture of — (P)	1007	and H. K. Perry. Water; Purification of — (P)	438, 1323r
Schmitz und Co. Camphor; Manufacture of — (P)	161r	Schulz, F. Mineral oil; Refining — by the dry process	1118
Schmücker, W. Fat extraction apparatus (P)	317	Rosin oil acids	805
Schneider, C. See Gary, M.	1250	Schulze, E., and C. Godet. Carbohydrates of plant seeds	1055
Schneider, E. Alloy for armour plates, &c. (P)	799r, 1091r	Schumacher, M. Lime mixtures which can be cast; Preparation of — (P)	1251
Steels; Treatment of — (P)	988r	Schumacher, W. Blast-furnace dust; Manufacture of briquettes from — (P)	889, 1045r, 1206r
Schneider, G., and E. Abresch. Copper; Extraction of — from ores, &c. (P)	1256	Iron ores; Briquetting fine spathic or other — (P)	798, 1143r
Copper ores; Leaching — (P)	1043	Schumann, A. Nickel; Electrolytic determination of —	43
Schneider, H. Disinfectants; Manufacture of — (P)	105r, 1000, 1061r, 1101r	Schuster, B. "Petroleum oder Elektrizität? Betrachtung z. Beleuchtungsfrage."	861
Schneider, J. Wool or other animal fibres and fabrics; Modifying the shrinking properties of — (P)	519	Schwalbe, C. G. Cellulose hydrates; Chemistry of —	216
Schneider, W. Chetrolime, an alkaloid from wallflower seeds	106, 1164	Hydrocellulose; Production of — by sulphuric acid	216
See Leuchs, K.	106, 905	Turpentine oil recovered in making sulphate-cellulose; Improving the odour of — (P)	851
See Rabe, P.	541	Vegetable fibres; Chemistry of —	743
Schneider et Cie. Steels for armour plate, &c.; Treatment of — (P)	608, 609r	Schwabenberg, E., and A. Rime. Artificial stone; Hardening — by carbon dioxide (P)	245r
Schmitz, J. See Henri, V.	954	Schwanninger, Y. Elevating liquids by means of gaseous fluids under pressure (P)	235, 601r
Schoeller, W., and W. Schrauth. Mercury derivatives of fatty acids; Preparation of salts of — and the anhydrides (P)	543, 1222	Schwartz, E. H., and Kroeschell Bros. Co. Crucible furnace (P)	247
Schoellkopf, J. F. Dyestuffs; Manufacture of coal-tar — in the United States	696	Crucible furnace; Gas-generating — (P)	207
and Schoellkopf, Hartford, and Haana Co. Cement; Waterproof — (P)	1132	Schwartz, M. Indigo dyes; Discharging — (P)	202
Schönberger, F. P. Calorific value of gases; Determination of the — (P)	261r	Schwartz, Y. Photographic paper (P)	492r
Schönfeld, F. Top-fermentation systems; German —	899	Schwarz, F. Mineral oil; Examination of — for fatty oil	468
and J. Dahncke. Stouts; Presence of yeasts which produce secondary fermentation in —	900	Petroleum oils of different origin; Differentiation between — and O. Weber. Formic acid in fruit juices; Determination of —	670
and W. Rommel. Beer yeast contaminated with lactic acid bacterin; Action of pasteurising temperatures on —	951	Schwarz, M. Resins, lacquers, varnishes, and driers; Preparation of transparent, coloured — (P)	1320
Schönmann, M. Liquids; Introduction of gases into — (P)	874	Schweitzer, A. Nickel; Electro-chemical behaviour of — (P)	989
Schofield, E. See Calico Printers' Association	201	Schwensen, C., and W. Lazarus. Malt; Saccharifying — (P)	1159
Schofield, J. A. Calco; Absorption of moisture by — Discussion	1022	Schwenzler, C. W. See Cummins, M.	22
Schoell-Schell, E. See Stadler, F.	890, 088r	Scoby-Smith, G. E. Gas producers for use in steel making (P)	359
Scholz, H., and Kautschukges. Schön und Co. Caoutchouc, gutta-percha, &c.; Production of pure — (P)	720r	Scott, E. G. Degreasing and cleaning fabrics, yarns, carpets, &c.; Apparatus for — (P)	201
Schoop, M. U. Aluminium; Flux for autogenous welding of — (P)	661r	Scott, R. W. Tin smelting; Methods and apparatus for — (P)	714
Aluminium objects; Welding or melting — (P)	26	Seaville, W. L. Gum tragacanth; Distinction of genuine — from spurious Indian gums	434
Aluminium welding —	607	Scurfield, G. G. Filters for oil, grease, &c. (P)	663
Schorr, R. Copper blast-furnace gases; Power from —	368	Seaman, W. H. Mercury; Determination of — in ores	650
Schon, E. Butter manufacture (P)	379r	Searle, A. B. Fireclay goods; Glazing of porous —	836
Cooling apparatus for fluids or semi-fluids (P)	1048	Seaver, J. M. Separating finely divided materials (P)	1113, 1307r
Soap; Manufacture of — (P)	482r	Seay, W. W. Refrigeration; Process of — (P)	786r
Schrade, J. L. Evaporating liquids; Apparatus for — (P)	131	Schillot, A. M. G., and L. Mauleclair. Gold; Extraction of — from its ores (P)	427
Schrauth, W. See Schoeller, W.	513, 1222	Metalliferous fumes produced in treating ores; Recovering — (P)	1143r
Schreiber, O. Impregnating material resembling rubber for millboard, textiles, &c.; Manufacture of — (P)	468	Sulphuric acid; Apparatus for making dilute — (P)	1197
Schreiner, O., and M. K. Sullivan. Soil fatigue caused by organic compounds	485	Seck, C. Separating and sorting materials (P)	501, 1024r
See D'Ans, J.	521	Security Savings and Trust Co. See Hall, E. L.	237
Schreyer, F. Copper ores; Basic converter process for —	426	Segalvie, I. Separators; Centrifugal — (P)	874
Schroeder, A. F. Sherardising apparatus (P)	1205	Seger, H., and E. Cramer. Bricks; Lime-inclusion in —	523
Schroeder, C. Lime; Continuous manufacture of finely-powdered slaked — (P)	524	Seger und Cramer, Chem. Lab. f. Tonind. u. Tonind-Zeit. Fusible bodies from silicate mixtures for temperature determinations (P)	1036
Schroeder, H. Phosphate; Preparation of citrate-soluble — (P)	102	Meadow-lime (Wiesenkalk); Burning — (P)	602
Schröder, K. Iron; Effect of copper on the Zimmermann-Reinhardt method of titrating —	110	Ségué, P. M. Alloy of copper, tin, zinc, and mercury (P)	1142
Thiocyanic acid; Determination of — volumetrically	1066	Electric batteries; Exciting liquid for — (P)	1206
Schroeder, W. G. Emulsions; Preparation of — (P)	78	Schmal, J. Lead sulphate; Solubility of —	555
Schroeter, C. F., and J. F. Hill. Coke oven (P)	643	Seidell, A. Salicylates; Determination of —	1166
Schryver, S. B., and R. Lessing. Disinfectants; Physico-chemical method for comparing the antiseptic value of —	60	Salicylates of the U.S.P.; Solubilities of the — in aqueous alcohol	1166
See Buchanan, G. S.	322, 956	Seidenschneur, F. Petroleum; Distillation of crude — (P)	613, 625, 795
Schubert, L. Starch in barley; Saccharification and polarimetric determination of —	487	Wood, Preservation of —	
Schulte, R. See Cassella, L., and Co.	470r	Seifert, B. K., and E. Merck. Fats; Manufacture of stable iodine compounds of — (P)	328r
Schüller, H. See Marcusson, J.	648	Seigle, A. Gold, platinum, silver, nickel, copper, &c.; Extraction of — (P)	428r
Schukoff, A. A. Oxidation of organic compounds (P)	383	Seisser, L. Coffee; Removal of caffeine from — (P)	622
Schulte, W. Antimony; Separation of — from solutions of chloroantimonates	545	Sejournet, P. See Soc. Electro-Metallurg. Franc.	1140
Schulte-Steinberg, H. Bricks from clay; Moulding — in the dry state (P)	1037	Selas-Ges., and F. W. Wöhl. Gas and air; Manufacture of a mixture of — (P)	1089r, 1117r
Schultze, W. Quicklime; Slaking — (P)	243, 522r	Selden, G. B. Fuel (P)	972
		Fuel for internal combustion engines (P)	920
		Selg, O., and C. Guntrum. Yeasts; Separation of inferior from normal — (P)	619

	PAGE		PAGE
Selvatici, E. Metals of the second group; Qualitative detection of —	1275	Siebert, Gebr. Waxed cloth, paper, &c.; Manufacture of — (P)	598
Sulphur in animal charcoal; Determination of total —	1008	Siefert-Schwab, E. Printing fabrics (P)	472
Selwig and Lange Maschinenfabr. Exhauster for acid gases (P)	235	Siegfried, M., and S. Howwjanz. Alcohols, sugars, and hydroxy-acids; Fixation of carbon dioxide by —	543
Semmler, F. W. Aldehydes; Enolisation of —	326	Siegle, G., and Co., and E. Württmer. Lakes from sulphonated azo dyestuffs (P)	532
Camphene; Constitution of —, and its oxidation by ozone	218	Siemens und Halske A.-G. Apparatus and tools; Manufacture of — (P)	829
Camphenil-aldehyde; Enolisation of —	441	Electrolysis of aqueous solutions; Apparatus for the — (P)	1144, 1145r
Carvenene; Inversion of — to isocarvenene	253	Incandescence bodies for electric lamps (P)	417r, 973r, 973r, 1117r
Carvenene and terpinene	1273	Incandescence bodies of tungsten; Manufacture of electric — (P)	83, 83r, 647, 647, 693r, 931r
Carvenene, C ₁₀ H ₁₆ , and "pure" terpinene	106	Metallic filaments; Removing carbon from — (P)	16r
enol-Citronellal acetate and its conversion into isopulegol	744	Metals; Apparatus for making homogeneous ductile bodies from refractory — (P)	799r
Eksantalal	326	Tantalum; Hardening — (P)	799r
enol-Isovaleraldehyde acetate	744	Tantalum; Manufacture of — (P)	480
Oenanthaldehyde acetate and enol-n-octanal acetate	542	Tungsten alloys; Manufacture of — and alloys of other refractory metals (P)	149, 481r
Terpinolene; Production of — by inversion of carvenene	441	Tungsten compounds; Manufacture of plastic masses from — (P)	16r
and E. Ascher. Carlina oxide	813	Tungsten; Increasing the ductility of — (P)	527, 609r, 1045r
Semper, M. G. Kiln; Rotary — (P)	131r	Zinc; Electrolytic production of — from zinc sulphate solutions (P)	1093r
Senderens, J. B. Ethers; Preparation of —	219	Zinc sulphate solution; Removing iron from — (P)	1047
Ketones; Catalytic preparation of —	489	See Fischer, E.	211r
Senn, H., and D. Klüger. Porous material; Manufacture of — from slate (P)	984, 1038r, 1038r	Siemens-Schuckert Werke. Mica; Softening — (P)	1317
Sensburg, L. Colloidal silver or silver oxide; Preparations containing — (P)	491	Siefert, P. T. Glass-making apparatus (P)	983
See Osborne, W.	328r	Glass plates; Manufacture of — (P)	601, 795
Senter, G. "Physical chemistry; Outlines of —"	224	Sieverts, A. Phosphorous and hypophosphorous acids; Reducing reactions with, and determination of —	1169
Separatorkaktiebolaget Mundus. Separators; Centrifugal — (P)	215	and J. Hagenacker. Nickel; Absorption of hydrogen by —	246
Sepulchre, F. Gases; Apparatus for purifying — (P)	973r	Sigmund, W. Enzymes capable of hydrolysing salicin and arbutin	258
Sepulchre, V. Gas producer for destroying refuse or gasifying fuels (P)	1187	Silber, P. See Ciamician, G.	547, 625
Serpek, O. Alumina; Reduction of — (P)	247	Silbermann, F. Chlorates and perchlorates; Electrolytic preparation of alkali — (P)	96
Aluminium nitride; Manufacture of — (P)	1198	Silberrad, O. Leather; Dressing of — (P)	1262
Ammonia from aluminium nitride; Production of — (P)	1126	Sillier, R. Hops; Chemistry of —	1056
Serrant, E., and A. Boileau. Explosives containing hypophosphites (P)	855	Silvester, H. Coal; Spontaneous heating of —. Discussion	772
Seward, G. O., and others. Metals and alloys; Reduction process for producing — (P)	146	Copper and brass industries; Chemist's relation to the —. Discussion	588
Silicon; Manufacture of — (P)	474	Copper; Influence of arsenic and antimony on —. Discussion	455
Seyde, F. See Bucherer, H.	650	Electrolytic analysis. Discussion	123
Seyewetz, A., and L. Meunier. Tanning or manufacturing leather; Process of — (P)	153r	University training of industrial chemists. Discussion	174
and L. Poizat. Hydrocyanic acid; Formation of — by action of nitric acid on phenols and quinones	219, 673	Silvestrini, N. Oil for use in painting; Substitute for — (P)	1050
See Lumière, A. and L.	109, 109, 627, 675, 746, 1223	Simon, A. Alumina; Manufacture of crystallised — from banxite (P)	309

Zink, W. A. H. See Hill, A. E.	163
Zitek, A. See Kremann, R.	653
Zoja, L. Egg-albumin and acetic acid; Interaction of — ..	111
Zubillaga, J. See Altolaguirre, M.	321
Zwick, H. Varnishes; Preparation of dipping — (P) ..	843, 993

INDEX OF SUBJECTS.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a patent.

Where the letter *r* follows number of page, it indicates that a reference only to a previous patent appears on that page; or, in the case of matter other than patents, that the subject is only referred to by title.

A

	PAGE
Abaca fibre; Tensile strength of —. Bacon	880
Abel heat-test; Committee to investigate the	444
Abrasive material. (P) Lersø	884
material. Manufacture of —. (P) Brightmore	984
products from aluminous earths; Manufacture of —.	
(P) Von Seemen	205 _r
Abrastol. See Calcium β -naphthol- α -sulphonate.	
Absorbent material for molasses, &c., from sawdust. (P) Cie.	
Ind. des Alcools de l'Ardèche	1023, 1024, 1114 _r
Absorbing towers; Liquid distributors for —. (P) Hom-	
mel, and Metals Extraction Corporation	1112
towers; Packing pieces for —. (P) Peyton	828
towers; Sprinkling device for —. (P) Klute and Ising	
.....	592
Acacia gum; Enzymes in —. Reintzer	1056
Acaroid resin; Red —. Andés	802
Accidents in factories, &c., in the United Kingdom, in 1908.	
First aid in chemical —. Nobel's Explosives Co.	1171
Accumulators. See Electric accumulators.	
Acetaldehyde in wine; Action of — on some other con-	
stituents. Trillat	668
Acetaminocantharumones; Preparation of —. (P) Bad-	
ische Anilin und Soda Fabrik	933
Acetate of lime. See Calcium acetate.	
Acetates Electrochemical manufacture of —. (P) Jacob	
.....	21, 208 _r
Manufacture of — from pyroigneous products. (P)	
Pages, Camus, et Cie., and Bardy	1320
Acetic acid; Electrolytic oxidation of ethyl alcohol to —.	
Askemay and others	1266
in Italy; Taxes on —	882
Manufacture of dihalogenated —. (P) Clayton Ani-	
line Co.	160
Acetic arsenious anhydride. Martindale	908
Acetic esters; Preparation of monohalogen —. (P)	
Imbert and others	815
Acetone and iodine; Dynamics of the reaction between —.	
Dawson and Leslie	1325
Manufacture of —. (P) Pages and Duchemin	1029 _r
Reaction of —. Bardach	673
Acetylcellulose; Dyeing —. (P) Knoll and Co.	1194
Plastic mass from —. (P) Bume	812
Acetyl chloride; Manufacture of dihalogenated —. (P)	
Clayton Aniline Co.	160
Acetylation; Acids as accelerators in —. Smith and Orton	
.....	678
Acetylene; Action of magnesium on —. Novák	1276
Elastic, plastic masses from —. (P) Horwitz	252
Fixing phosphorated hydrogen in —. (P) Soc. Com-	
merce, du Carbone de Calcium	237, 830, 835 _r
Preparation, storage, and use of —	786
Purification of —. (P) Jouve	830
Acetylene tetrachloride; Manufacture of —. (P) Chem.	
Fabr. Griesheim-Elektron	109 _r
Acid burners; First aid treatment of —	1171
gases; Exhauster for —. (P) Schweg and Lange	
Maschinenfabr.	235
-proof materials; Manufacture of —. (P) Roberts ..	
in tannery liquors; Determination of — by the gelatin-	
hematin method. Alsop	721
Acid chlorides; Manufacture of organic —. (P) Meister,	
Lucius, and Brünig	815
Acid Green. See under Triphenylmethane dyestuffs.	
Acids; Action of sulphur monochloride on salts of organic	
Denham	813
Apparatus for use in making —. (P) Firman and Cock-	
ledge	707
of the body of the silk-worm moth; Mono-amino —.	
Abderhalden and Weichardt	518
of butter fat and coconut oil; Metallic salts of the vola-	
tile fatty —. Paal and Amberger	157
of Canton silk; Mono-amino —. Abderhalden and	
Behrend	517
condensing and absorbing vapours of volatile —. (P)	
Scherfberg and Trager	90
Continuous concentration of —. (P) Aktiebolaget	
Swedish Nitrate Synd.	1137

Acids—cont.

	PAGE
Determination of volatile — in wines. Malvezin	435
fatty, of butter fat and coconut oil; Distillation of —.	
Caldwell and Hurlley	315
fatty; Compounds of — with aldehydes and ketones,	
and their use in colour printing. (P) Meister,	
Lucius, and Brünig	519, 1063 _r
fatty; Conversion of liquid into solid —. (P) Sabatier	
fatty; Converting unsaturated — or their esters into	
saturated compounds. (P) Erdmann	044
fatty; Decolorising and purifying — obtained from	
waste waters of dyeworks, &c. (P) Planowsky and	
Philippoll	980
fatty; Determination of — in soap:	
Dominikiewicz	801
Fendler and Frank	250
fatty; Determination of — in soap stock	1210
fatty; Fermentation process to obtain — from nitro-	
gerous substances. (P) Elfront	35
Fatty — of fish oils. Tolman	716
fatty; Manufacture of amides of —. (P) Kösters and	
Ottmann	442 _r
fatty, of marine animal oils; Oxidised —. Tsujimoto	
fatty, of marine animal oils; Resinous substance de-	
posited from — on keeping. Tsujimoto	316
fatty; Preparation of hydroxy-chloro derivatives of —.	
(P) Cons. f. Elektrochem. Ind., and Imbert	945
fatty; Salts of mercury derivatives of —. (P)	
Schoeller and Schranth	543, 1222
fatty; Separation of mixtures of some —:	
Hodgson	1170
Keane and Narracott	1170
fatty; Separation of solid from liquid —:	
(P) Barbé and others	663 _r
(P) Twitcheil	532
fatty; Transformation of liquid into solid —. (P)	
Barbé and others	663 _r
Fixation of carbon dioxide by hydroxy- —. Siegfried	
and Howewjanz	543
Influence of sodium salts on solubility of some —.	
Philip and Garner	1104
Manufacture of —. (P) Tufts, and Merrimac Chemical	
Co.	981
Mono-amino — from Niét ngu tsâm, Indian tussah, and	
Canton silks. Abderhalden and others	1083
of New Chwang silk; Mono-amino —. Abderhalden	
and Rilliet	240
Raising — by compressed air, &c. (P) Rayne	235
of rosin oil. Schulz	895
in tobacco; Determination of volatile organic —.	
Kissling	819
in vinegar; Determination of mineral —. Repton ..	
in wine and vinegar; Apparatus for determining —.	
Gore	1274
Aconite. Taylor	1002
root and preparations; Alkaloidal valuation of —.	
Bernegau	439
Aconitine from Japanese aconite tubers. Makoshi	623
Acyllaminophenylarsinic acids; Preparation of —. (P)	
Meister, Lucius, and Brünig	107
Acyllaminophenyl- and tolylarsinic acids; Preparation of	
carboxylic acids of —. (P) Meister, Lucius, and	
Brünig	108
Acylyl-p-diamines; Manufacture of aromatic —. (P) Kalle	
und Co.	791
Acylsalicylic anhydride. (P) Bayer and Co.	675 _r
Adrenaline; Iodic acid reaction of —. Krauss	1273
reaction; A characteristic —. Fraenkel and Allers	
See also Suprarenin.	
African food grains; Some —	998
vegetable fats — Krause and Diesselhorst	882
Acave fibres from India	651
Acaves; Cellulose and nitrocellulose from —. Carneiro ..	
.....	384
Agglomerating powdered or friable substances. (P) Delporte	
Process of —. (P) Ronxeville	874
Agitating liquid compounds; Machinery for —. (P)	
Skinner and others	464
mixtures of solids and liquids. (P) Carriek and Pattison	
.....	236, 300 _r
Agostini process; Treatment of yarns and fabrics by the —.	
Prudhomme	652

	PAGE
Agriculture; Use of zeolites and similar compounds in — Gans	102
Air; Apparatus for compressing —. (P) Fletcher	1079
Apparatus for liquefying —: (P) Bobrick, and U.S. Liquid Air and Oxygen Co.	982
(P) Place	310r
(P) Place, and American Air Liquefying Co.	939
Apparatus for separating oxygen from —. (P) Johnson	1035
Apparatus for supplying heated —. (P) Farbridge	509
Apparatus for treating — electrically: (P) Bridge	1144
(P) Mitchell	989
-blast for metallurgical furnaces; Drying the —. (P) Harbord	369
Centrifugal apparatus for separating solid matters from —. (P) Lebrasseur and others	929
Composition for purifying —. (P) Ryder and Wilson	1057
Compressing —. (P) Humphrey	300r, 784
Determination of carbon dioxide in —. Davies and McLellan	232
Drying —: (P) Baker	874
(P) Gardner	300
Drying — for metallurgical purposes. (P) Block	1316
Extraction of nitrogen from —. (P) Blagburn	794
Increasing the proportion of oxygen in —. (P) Tavernier	365
Liquefying — and separating it into its constituents. (P) Soc. l'Air Liquide	1127
of mines; Impurities in — due to firing dynamite. Nauckhoff	816
mixture of a high ratio of oxygen; Production of an —. (P) Brinler	365r
Ozonising —. (P) Williams and Glascock	787
Production of liquid —. (P) Place, and Amer. Air Liquefying Co.	522r
Production of nitrogen from —. (P) Hurford	243, 365r
propelling and ozonising apparatus. (P) Craig	297
Separation of — into its constituents: (P) Bobrick	140
(P) Soc. l'Air Liquide	884, 1127
(P) U.S. Liquid Air and Oxygen Co.	939, 939r
Separation of — into its elements by fractional distillation. (P) Hazard-Flamand	310
Testing —. (P) Arndt	1323
<i>Ajuga iua</i> . Ponti	1324
Alamosite, a new lead silicate from Mexico. Palache and Merwin	606
Albumin and acetic acid; Interaction of egg —. Zoja ..	111
-arsenic compound; Preparation of an —. (P) Klopfer	1223
Drying —. (P) Schmitt and Ahrens	437r
Hydrolysis of egg — with sodium hydroxide. Skraup and Hummelberger	436
Treatment of vegetable — and animal casein. (P) Wichmann, and Protal Co.	1060r
Albuminoid materials; Treatment of —. (P) Desgeorge and Lebreil	153
Albuminoids; Dissolving —. (P) Chavassieu	422, 1152r
Strengthening materials composed of —. (P) Eschaler	362, 1121
Treatment of —. (P) Ekströmer and Ekströmer	810r
Albumose; Preparation of —. (P) Runge	1105
and silver; Basic compounds of —. (P) Schering	1062
Alcohol; Action of — and its impurities and denaturant, on common metals. Duchemin	736
Application of the diastases of unmaltd cereals to the preparation of —. Tanaka	376
from "blackboy"; Production of —. (P) Wallace and Reynaud	255
denatured; Formula for making chloral hydrate in the United States	35
Denatured — for power, lighting, and heating. (P) Novel	16
denatured; Production of — in the United States	214
denatured; Use of — in chemical industries	953, 955
Denaturing and carburetting —. (P) Durupt	1217
Detection of methyl alcohol in ethyl —. Vorisek	823
Developing a mature flavour in —. (P) Rousset	998
Electric conductivity of mixtures of — and water. Doroshewski and Roshdestwenski	853
Electrolytic oxidation of ethyl — to acetic acid. Askensy and others	1266
Fixation of nitrogen by — by means of silent discharges. Löb	1005
Formation of butyric acid from — by silent discharges. Löb	1004
in France; Manufacturing tax on —	732
<i>Helianthus</i> tubers as material for the production of —. Kocks	487
Highly carburetted — as motor fuel. Mohr	692
for making sodium hydrosulphate; French denaturation tax on —	1085
Manufacture of —: (P) Gailhat	153
(P) Woolner and others	737
Manufacture of — from maize-cobs. (P) Stewart and Gill	737

	PAGE
Alcohol—cont.	
Manufacture of solidified —. (P) Perclzveich and Rosenbusch	514r, 693r
Manufacture of — from sulphite-cellulose waste liquors. (P) Stora Kopparbergs Bergslags Aktiebolag	1221
from peat; Manufacture of —. (P) Soc. Anon. Origo in the Philippines; Industrial —. Cox	35, 1057
Preparing nitrogen hydrosulphide for carburetting —. (P) Barbier	592
Purification of crude —. (P) Hager	488r
Recovery of — from the air in making powder, artificial silk, &c. (P) Crépelle-Fontaine	1078
Recovery of — when mixed with air. (P) Soc. l'Air Liquide	880
Recovery of — from sulphuric acid used in making artificial silk. (P) Crépelle-Fontaine	597
from sawdust and other wood waste. Rutlan	1290
Specific heat of — and of its mixtures with water. Doroshewski and Rakowski	853
statistics; French — for 1908	1099
from straw; Manufacture of a liquid suitable for producing —. (P) Giles and Norris	538
Tax-free, denatured, grain — in manufacture of dyestuffs in the United States. Prochazka	696
Transforming — for use as fuel. (P) Manger	237, 467r
for use in making butyric and formic esters	960
Alcoholic fermentation. <i>See under</i> Fermentation.	
liquids; Distilling and rectifying —. (P) Slavicek	377, 1159r
liquors; Action of hydrogen peroxide on —. Chauvin	997
liquors; Maturing and purifying —. (P) Haack	1218r
liquors; Prohibition of import of — into Iceland	936
Alcoholometers. (P) Desq	619
Alcohols; Action of — on calcium. Perkin and Pratt	220
Apparatus for distilling —. (P) Vallat	1267r
Catalytic action of metallic salts in the decomposition of —. Chavanne	814
Differentiation between primary, secondary, and tertiary —. Wacker	898
Distillation of —. (P) Waterhouse	1322
Distinguishing between primary, secondary, and tertiary — by the Sabatier-Senderens test. Neave	912
Fixation of carbon dioxide by —. Siegfried and Howwanz	543
Oxidation of polyhydric — by a peroxydasic system. De Stoecklin and Vulquin	678
Oxidation of — by simultaneous action of iron tannate and hydrogen peroxide. De Stoecklin	327
and salicylic esters; Manufacture of mixed carbonates of hydro-aromatic —. (P) Bayer and Co.	259
and water; Refractive indices of mixtures of —. Doroshewski and Dworzanczyk	853
Aldehyde from turpentine. Harries and Splawa-Neyman ..	410
Aldehyde-bisulphites; Nitrogen derivatives of —. (P) Chem. Fabr. von Heyden	1326
Aldehydes and amines; Electro-chemical reduction of condensation products of —. Brand	1103
Compounds of — with acids. Shukow and Kassatkin	673
Enolisation of —. Semmler	326
and fatty acids; Compounds of — and their use in colour printing. (P) Meister, Lucius, and Brünig ..	519, 1063r
in lemon oil; Determination of —. Bennett	159
Manufacture of —. (P) Ellis and McElroy	412
Oxidation of — by silver oxide. Delépine and Bonnet	853
and phenols; Condensation of — to resinous products. (P) Helm	995
and phenols; Hardening condensation products of —. (P) Knoll and Co.	803, 843r
Preparation of aromatic — having at least one hydroxy-group adjacent to the aldehyde group. (P) Kalle and Co.	675
Reaction for —. Franzen	1167
Synthesis of aromatic —. Guyot	1273
Aleppo pine; Resinous exudation of the —. Vèzes	1050
<i>Alge</i> ; Manufacture of extracts of marine —. (P) De la Guéronnière	999
Alimentary products. <i>See under</i> Foods.	
Alizarin. <i>See under</i> Anthracene dyestuffs.	
Alkali; Apparatus for recovering —. (P) Logan	203
-chlorine cell; Efficiencies of the Finkay electrolytic —. Donnan and others	521
industry; Electrolysis in the —. Lepsius	1123
ac., works; 45th annual report of the Chief Inspector, for 1908	702
Alkali aluminates; Manufacture of —. (P) Peniakoff	425, 600r
bicarbonates. De Forcerand	1312
carbonates; Manufacture of —. (P) Rivière	599, 707, 937, 1197
chloride solutions; Apparatus for electrolytic decomposition of —. (P) Rink	522r
chlorides; Electrolysis of —. (P) Billitzer	884
cyanide; Determination of sulphide in —. Ewan ..	10
hypochlorite solutions; Electrolytic preparation of —. (P) Düring	1126
(P) Elektrizität A.-G. vorm. Schuckert and Co.	1126
hydrosulphites; Manufacture of —. (P) Badische Anilin und Soda Fabrik	90, 310r
(P) Bayer and Co.	90, 90r, 310r, 600r, 708, 1087r

	PAGE		PAGE
Alkali—cont.		Almond flavouring extract; Determination of benzaldehyde in —. Denis and Dunbar	488
hydroxide; Electrolytic manufacture of — and bromine. (P) Kossuth	835	Aloes from Sicily. Condo-Vissicchio	440
hydroxides; Electrolysis of fused —. Von Hevesy	802	Aloin and ferrie compounds; Compounds soluble in alkali from —. (P) Dieffenbach and Meyer	674
hydroxides; Manufacture of —. (P) Gibbs	204	Alum; Manufacture of iron-free —. (P) Strobach	982r
iodides; Determination of —. Rupp and Penning	444	Sodium —. Smith	242
peroxides; Package for preserving —. (P) Herrmann	880, 930r	Alumina; Preparation of —. Kremann and Hüttinger ..	1124
polysulphides; Determination of sulphur in —. Dussere and Vuilleumier	1220	Alumina; Calcining hydrated —. (P) Vergé	310
salts; Electrolysis of —. (P) Marie	1092	Manufacture of —; (P) Hall, and Aluminium Co. of America ..	600
salts; Manufacture of —. (P) Vasceux	153r	(P) Mculloch, and Aluminium Co. of America ..	1249
silicates; Manufacture of —. (P) Soc. Electrometall. de St.-Béron	22	Manufacture of crystallised — from bauxite. (P) Simon in phosphate rocks; Determination of —. Gladding ..	309
thiosulphates; Manufacture of —. (P) Destree et Cie. ..	473	Recovery of soda in making —. (P) Peffer, and Aluminium Co. of America ..	1249
Alkali-cellulose, Constitution of —. Miller	37	Reduction of —. (P) Serpek	247
Alkali-metal amalgams; Apparatus for decomposing —. (P) Carrier	147	Removal of silica in making —. (P) Peffer, and Aluminium Co. of America ..	1249
Alkali-metals and platinum; Alloys of —. Hackspill	714	and silica; Composition containing —. (P) Tone, and Carborundum Co. ..	21
Suspension of carbon in —. (P) Weintraub, and General Electric Co.	704	with silica, lime, and magnesia; Binary systems of —. Shepherd and others	1124
Alkaline-earth hydrosulphides; Manufacture of —. (P) Coulier	22	Aluminates; Manufacture of —. (P) Gibbs	310r
silicides. Högnschmid.	941	Manufacture of alkali —. (P) Peniakoff	425, 600r
Alkaline; Electrolytic manufacture of — and salts. (P) Girard	1313	Aluminium; Action of acids on —. Schoop	007
in silicates; Determination of —. Starck	882	Action of hydrochloric acid gas on —, and analysis of aluminium. Kohn-Abrest	839
Alkaloid from bark of <i>Pseudocinchona Africana</i> . Fournieu ..	812	alloy; Unoxidisable —. (P) Etienne	087
Alkaloidal extracts; Deterioration of — by keeping. Ribaut	439	alloys; Light —. (P) Soc. Anon. le Ferro-Nickel ..	1205

Alundum; Manufacture of —	1088
Amalgams of alkali-metals; Apparatus for decomposing —. (P) Carrier	147
Amapa milk: Composition of —. Rathje	159
Amazon Valley; Rubber crop of the —	994
Amber; Artificial — from copals. (P) Spiller	483
Amé; Application of the diastases of unmalted cereals to the preparation of —. Tanaka	376
America; Lactic acid in —. McLaughlan	734
Anides of higher fatty acids; Manufacture of —. (P) Kösters and Ottmann	442r
Amines and aldehydes; Electro-chemical reduction of condensation products of —. Brand	1103
Diazotisation of weakly basic, sparingly soluble, primary —. Witt	1081
Preparation of sodium and potassium compounds of primary and secondary aromatic —. (P) Basler Chem. Fabr.	161
and sodium; Preparation of compounds of aromatic —. (P) Deuts. Gold-u.-Silber-Scheide-Anstalt	1223
Aminoacetylcatechols; Manufacture of —. (P) Bayer und Co.	1104
Aminoarylsarlnic acids; Acid derivatives of —. (P) Meister, Lucius, und Brüning	107, 491r, 1223r
<i>p</i> -Aminobenzoic acid isopropyl ester. (P) Bayer und Co.	854, 1223r
<i>n</i> -propyl ester. (P) Fritzsche und Co.	814, 854r
<i>o</i> -Aminobenzonitrile and its substitution products; Preparation of —. (P) Kalle und Co.	933
Amino-compounds and hydrazines; Condensation of aromatic —. (P) Bucherer und Seyde	650
Amino-derivatives of benzene; Home Office regulations for the manufacture of —	134
<i>p</i> -Aminodiazobenzene and its derivatives; Preparation of —. (P) Badische Anilin und Soda Fabrik	86
Aminomethylenecatechol; Hydroxyazo derivatives of —. Mamel	1119
Aminonaphthylarsonic acid. Martindale	911
1-Aminonaphthalene-4,7-disulphonic acid and 2,4,7-trisulphonic acid; Preparation of —. (P) Meister, Lucius, und Brüning	1246
4-Amino-2-utrobenzoic acid; Manufacture of —. (P) Meister, Lucius, und Brüning	85
<i>p</i> -Aminophenol; Arylalkyl —. (P) Rehländer und Schering	675r
Manufacture of — and its derivatives. (P) Act.-Ges. f. Anilinfabr.	698r
Separation of — from methyl- <i>p</i> -aminophenol. (P) Act.-Ges. f. Anilinfabr.	491
<i>p</i> -Aminophenols; Arylalkyl derivatives of substituted —. (P) Schering	1104
Aminophenylarsinic acid and its derivatives; Derivatives of —. (P) Mouneyrat	1167
<i>m</i> -Aminophenylarsinic acid; Preparation of —. (P) Meister, Lucius, und Brüning	328
<i>p</i> -Aminophenylarsinic acid; Acyl derivative of —. (P) Meister, Lucius, und Brüning	42r
Azo dyestuffs from —. (P) Act.-Ges. f. Anilinfabr.	960
Manufacture of homologues of —. (P) Meister, Lucius, und Brüning	107, 383r
Manufacture of sulphur derivatives of —. (P) Meister, Lucius, und Brüning	220
Mercury salt of —. (P) Act.-Ges. f. Anilinfabr.	1273
(P) Bayer und Co.	442, 491r, 960r
(P) May and Baker, and Bates	442
Aminophenylarsinic acids; Manufacture of acyl derivatives of —. (P) Meister, Lucius, und Brüning	107
<i>p</i> -Aminophenylarsonic acid, its salts and derivatives. Martindale	910, 911
<i>p</i> -Aminophenylarsonic toluenesulphonate. Martindale	911
<i>p</i> -Aminophenyl-2-azimino-5-naphtholsulphonic acid and azo dyestuffs therefrom. (P) Soc. Chem. Ind. in Basle	596r
2-Aminotolyl-5-arsonic acid. Martindale	911
Ammonia from aluminium nitride; Production of —. (P) Serpek	1126
from coal-gas; Recovery of —. (P) Collin	1027
Electrolytic oxidation of —. Brochet and Bouteau	704
Extraction of — from ammoniacal liquor. (P) Herri	1243
Formation of hydrocyanic acid from — and wood charcoal. Voerkelius	1122
from gas-liquor; Apparatus for recovering —. (P) Berlin-Anhalt. Maschinenbau A.-G.	84, 468
Gas producer plant for recovering —. (P) Crossley and Rigby	930
and magnesium salts; Manufacture of —. (P) Hüfner	1034
Manufacture of —. (P) Badische Anilin und Soda Fabrik	243r, 309
(P) Feriche	21, 600r, 1314r
(P) Koppers	695
(P) Krauss, und Ges. f. Stickstoffdünger	657r
Manufacture of — with chlorine or hydrochloric acid. (P) Whitehouse	794r

Ammonia—cont.	
Manufacture of pure — from ammonia liquors. (P) Stine, and Du Pont de Nemours Powder Co.	974
Manufacture of synthetic —. Bronnert	433
from nightsoil; Apparatus for recovering —. (P) Fryk-lind	810
from organic nitrogenous substances; Fermentation process to obtain —. (P) Eiffont	35
from producer-gas; Plant for recovering —. (P) Lynn	513
production of Great Britain in 1908. Bradbury and Hirsch	90
production of the United States. Parker	1028
Pyrrrole as impurity in —. Brandt	1169
Recovery of — from gases produced in dry distillation. (P) Act.-Ges. f. Kohlendestillation	516, 693r
Solid hydrates of —. Rupert	936
solution; Detection and determination of pyridine in —. Pinchbeck	202
solution; Determination of pyridine in —. Houghton	1195
Synthesis of — from its elements. Lipski	423
Synthesis of — by means of peat. Wolterbeck	20
and zinc compounds; Recovery of — from galvanisers' skimmings. (P) Pearlman	522
Ammonium chlorate; Cheddites containing —	221
chloride, lead chloride, water; Equilibria in the system —. Brönsted	707
chloride; Manufacture of — from ammonium sulphate and sodium chloride. (P) Neumann	140r
chloride and sodium sulphite; Manufacture of —. (P) Friedrich und Co.	1034, 1249r
hydrosulphide, sulphide, and polysulphides. Bloxam	138
nitrate crystals; Apparatus for making —. (P) Knowles and Malone	1034
nitrate explosives; Experiments with — at Schwalbach	42
nitrate explosives; Plastic —. (P) Verein. Köln-Rottweiler Pulverfabr.	1328
nitrite; Decomposition and sublimation of —. Rly	308
phosphate; Determination of — volumetrically. Wilkie	980
phosphate; Manufacture of stable —. (P) Caro and Scheele	724, 939r
salts; Direct assimilation of — by plants. Hutchinson and Miller	1213
salts and ferric oxide; Manufacture of — from ferrous liquors. (P) Carulla	1126
sulphate; Apparatus for granulating, drying, and screening —. (P) Soc. du Gaz de Paris	1198
sulphate from distillation gases; Extraction of —. (P) Gewerkschaft der Steinkohl-nische Mont Cenis	1308
sulphate in Japan	883
sulphate; Manufacture of —. (P) Erlenbach	708r, 794r
sulphate from peat; Manufacture of —. (P) Dromain	17
sulphate; Saturator for making —. (P) Brotherton and Wyld	974
(P) Koppers	790
sulphate; Treatment of —. (P) England	724
sulpho-phosphate; Manufacture of —. (P) Hubert	938
Amorphophallus roots and tubers; Rendering insoluble the mucilaginous substances in —. (P) Mertens und Co.	103, 1157r
Amyl acetate for celluloid factories in Holland.	913
Amylaceous materials; Treatment of —. (P) Boidin	997, 1265r
<i>iso</i> -Amylarsonic acid. Martindale	908
Amylase in old grain; Presence of —. Brocq-Roussen and Gain	262
Anaerobase in cows' milk; Presence of an —. Sarthou	1160
Analysis; Apparatus used in rapid methods of electrolytic —. Price and Humphreys	117
Destruction of organic matter in chemico-legal — by Gasparini's electrolytic method. Miorandi	330
Effect of colloids in —. Alexander	285
Electrolytic; Report of Brit. Assoc. Committee on —	1067
Iron alum as standard in volumetric —. De Koninck	817
Rapid electrolytic —. Filippo	545
Use of mercury cathodes in electrolytic —. Böttger	677
Use of sodium peroxide in organic —. Pringsheim	44
Anhydrides of aromatic sulphonic acids. Meyer	1104
Manufacture of organic —. (P) Meister, Lucius, und Brüning	815
Mercury derivatives of fatty acid —. (P) Schodler and Schranth	543, 1222
of organic acids; Preparation of —. Denham	813
Anhydromethyleneitic acid esters; Preparation of —. (P) Bayer und Co.	490, 675r, 854r
Aniline; Action of potassium hydroxide on —. Baeovescu	1080
derivatives; Toxicity of certain —. Hildebrandt	1103
Manufacture of — and its derivatives. (P) Act.-Ges. f. Anilinfabr.	698r
poisoning. Factory Inspector's Report	753
Aniline Black. Willstätter and Dorogi	695, 1244
Chemical technology of —. Green	700
Constitution of —. Bucherer	1082
printing; White reserves for indanthrene dyestuffs in conjunction with —. Razzkowski	597

Cadmium amalgams. Smith	1257
nrc; Production of a —. Lowry	1091
Electrolytic determination of —. Holmes	43
in soft solders. Sperry	650
Cadmium sulphate; Solubility of — under pressure. Cohen	981
Caffeine in coffee and its loss on roasting. Lendrich and Nottbohm	1058
from coffee; Removal of —. (P) Selaser	622
Determination of — in coffee. Lendrich and Nottbohm	379
Error in determining — by Juckenaek and Hilger's method. Lendrich and Mordfeld	36
Calamines; Calcining and enriching poor —. (P) Babé	1044
Calcination; Process of —. (P) Heckman and Gilmore	646
Calcining apparatus. (P) De Jonge and Nevers	78
mineral or organic materials. (P) Pagès, Camus, et Cie., and Bardy	594

Calcium; Action of alcohols on —. Perkin and Pratt	220
alloys as reducing agents. Watts and Suhm	659
Determination of small quantities of — in presence of much magnesium. Hundeshagen	363
Heat of combustion of —. Weston and Ellis	94
Separation of — from magnesium. Blasdale	961
-silicon alloys. Tamaru	526
-silicon alloys; Manufacture of —:	
(P) Goldschmidt and others	97, 1316
(P) Willson and Haft	1087
Calcium acetate; Analysis of commercial —. Gladding	467
acetate; Manufacture of —. (P) Erwin	879
-alkali sulphates. D'Ans and Schreiner	521
-antimony lactate; Preparation of —. (P) Chem. Werke Schuster and Wilhelm	1326
bromide; Volatility of —. Stock and Heynemann	1248
carbide cartridges. (P) Barnett	1117
carbide; Grinding —. (P) Cyanid-Ges.	845
carbide; Manufacture of —. (P) Seymour	474
carbide; Storage of —	786
See also Carbide.	
carbonate; Dissociation of —. Zavrjeff	137
carbonate in soils; Determination of —. Marr	1213
carbonate; Treatment of minerals containing —. (P) Buendia	884
chloride; Reactions of — in methyl acetate solutions. Naumann	1196
chloride; Solutions of lime and silica in fused —. Arndt and Löwenstein	1124
citrate; Analysis of —. Gadais and Gadais	440
cyanamide	139
Acby	252
Prianichnikov	724
cyanamide; Decomposition of — in the soil:	
Kappen	153
Lönnis and Moll	153
cyanamide; Formation of —. Foerster and Jacoby	1248
cyanamide; Gaseous decomposition products of —. Haselhoff	433
cyanamide; Granulation of powdered —. (P) D'Ercle	666
cyanamide and nitrate; Manurial values of — for sugar beet. Urban	666r
dibromobenzene. (P) Bayer and Co.	544r
<i>o</i> -naphthol- <i>g</i> -sulphonate; Reaction of —. Carletti	852
nitrate; Manufacture of nitric acid from —. (P) Chem. Werke vorm. H. Byk	365
nitrate; Reactions of — in methyl acetate solutions. Naumann	1196
oxalate; Manufacture of —. (P) Hempel	365
phosphate; Manufacture of — together with magnesia and potassium chloride. (P) Schloesing	242
phosphate; Manurial experiments with precipitated —. Söderbaum	1097
phosphates; Enriching —. (P) Bardy	1054
phosphates; Phase-relationships of the —. Bassett	722
phosphide; Manufacture of amorphous —. Munroe	364
phosphide; Rapid preparation of —. Matignon and Trannoy	203
silicide; Manufacture of —:	
(P) Goldschmidt	97, 1316
(P) Willson and Haft	1087
silicides and their capacity for absorbing nitrogen. Kolb and Formals	1313
soaps; Colloidal solutions of — in heavy mineral oils. Holde	98
sucrate; Apparatus for making —. (P) Pool, and American Sugar Refining Co.	486
sucrate in milk; Detection of —. Rothenfusser	956
sulphate; Behaviour of — with some fluxes at high temperatures. Hofman and Mostowitsch	246
sulphate; Treatment of waste hydrated —. (P) Eastwick	205r
sulphates; Double —. Barre	705
Calendering machines. (P) Bemberg A.-G.	653
Caliche; Lixivating apparatus for extracting sodium nitrate from —. (P) Love	708
Calico printing. (P) Calico Printers' Assoc., and Davis	1031
printing; Cheap blues for —. Steiner	199
-printworks; Decolourising and purifying fatty acids from soapy waters of —. (P) Planowsky and Philippoff	980
California; Petroleum production in —	593
Sodium sulphate deposit in —	655
Calorific power of gases; Determining the —. (P) Lemoit, and Poulenc frères	817
value of gas mixtures; Apparatus for measuring and indicating the —. (P) Evans	627
value of gases; Determination of the —. (P) Schönbberger	261r
Calorimeter. (P) Emerson	1007
lamp. (P) Junkers	544
Calorimetry; Gas —. Coste	1231
Camembert cheese. See under Cheese.	
Camphene; Constitution of —. Semmler	218
Manufacture of —:	
(P) Act.-Ges. f. Anilinfabr.	220, 382, 626r
(P) Glaser	745
Manufacture of — from borneols. (P) Schering	854
Manufacture of — free from chlorine. (P) Roessler	161

	PAGE		PAGE
Camphene— <i>cont.</i>		Carbon— <i>cont.</i>	
Manufacture of — from pinene hydrochloride. (P) Wendt	442	electrodes; Manufacture of —. Roush	609
Manufacture of — from liquid pinene hydrochloride. (P) Clayton Aniline Co., and others	259	for filaments; Manufacture of —. (P) General Electric Co., and Whitney	467r
Oxidation of — by ozone. Semmler	218	Manufacture of finely divided amorphous or crystalline —. (P) Gollmert	1050
Camphenilaldehyde; Enolisation of —. Semmler	441	Ordinary —. Le Chatelier and Wologdine	1196
Camphol esters; Manufacture of —. (P) Verley and others	108r	Recovery of pure — from pitch, tar, asphaltum, &c. (P) Chem. Fabr. Lindenhof C. Wyl und Co.	1119
Oxidising — to camphor. (P) Verley and others	109r	Suspension of — in alkali metals. (P) Weintraub, and General Electric Co.	794
Campholic acid; Racemic —. Guerbert	440	Carbon bisulphide in benzene; Determination of —. Weiss	974
Camphor; Action of phenylmagnesium bromide on —. Creighton	218	from coal gas; Removal of —. Matwin	829
Action of potassium hydroxide on —. Guerbert	440	from gases; Removal of —. (P) Mayer and Fehlmann	830
Chinese —	1272	Carbon chlorides; Utilisation of —. (P) Pichon and Truchelat	1273
Complete synthesis of —. Komppa	106	Carbon dioxide; Absorption of — by charcoal. Geddes in the atmosphere; Rapid determination of —. Davies and McLellan	1009
Determination of — in spirit of camphor. Denssen	906	Decomposition of — by the silent electric discharge. Holt	232
Differences between natural, artificial, and synthetic —. Lohmann	671	Decomposition of — by ultra-violet rays. Herche-finkel	27
exports from Formosa	440	Fixation of — by alcohols, sugars, and hydroxy-acids. Siegfried and Howwranz	963
exports of Japan	913	and lime; Manufacture of —. (P) Thom and Pryor	543
Manufacture of —:		recorders for flue gases, &c. (P) Carr	1087
(P) Ansterweil	745r	Retort furnaces for making —. (P) Thom and Pryor	1117
(P) Glaser	1006r	Separation of — from gaseous mixtures. (P) Behrens	1125
(P) Hertkorn	746r	Carbon monoxide; Determination of — in mine gas. Weiskopf	938
(P) Schmitz and Co.	101r	Determination of — together with hydrogen and methane. Nesmejow	1170
Manufacture of artificial —. (P) Le Roy	41	Illuminating efficiency of — compared with hydrogen for incandescence lighting. Forshaw	465
Manufacture of sticks, tablets, and filaments of —. (P) Sehering	814, 1063r	Pyrogenetic oxidation of — by contact action. Orlov	786
Oxidising camphol to —. (P) Verley and others	103r	Carbon suboxide; Preparation of —. Staudinger and St. Berez	424
Rapidity of volatilisation of —. La Wall	1103	Carbon tetrachloride; Apparatus for extracting fatty matters by —. (P) Bernard	107
substitutes. Analysis of camphorated oil for —. Richardson and Walton	40	Examination of —. Radcliffe	209r
from turpentine oil; Manufacture of —. (P) Mayer	108	Use of — in determination of fat. Rammstedt	229
Camphorated oil; Analysis of — for camphor substitutes. Richardson and Walton	40	Carbonaceous materials; Briquetting —. (P) Griffin and others	16
Camphoric anhydride; Preparation of —. Edgerton	62	substances; Distillation of —. (P) Parker	304r, 515, 879, 1308r
Canada; Cement production and consumption of —	710	Carbonates; Determination of — in presence of nitrites, sulphides, or sulphates. Marle	627
Mineral production of — in 1908	387	Formation of graphite by action of magnesium on —. Ellis	83
Peat industry of —	1024	of some heavy metals. Feist	1195
Canadian Fertilisers Act, 1909	805	Manufacture of alkali —. (P) Rivière	599, 707, 937, 1197
pulp and paper	743	Carbonator. (P) Keele and Rampp	971
Candle making machinery. (P) Plumbridge	1259	Carboniferous substances. Charitschkow	237
Candles; Manufacture of paraffin wax for —. (P) Finlay	1119	Carbonising furnaces. (P) Lorenz	133
Manufacture of stearine —. (P) Comp. Luz Stearine	251, 1094r	mineral or organic materials. (P) Pagès, Camus, et Cie., and Bady	594
Porcelain mould for —. (P) Lewy	612	peat and similar substances. (P) Oberbayerische Koks-werke n. Fabr. Chem. Prod.	1240
Cane molasses. <i>See under Molasses.</i>		rags, &c.; Machine for —. (P) Fitton	934
sugar. <i>See under Sucrose and Sugar.</i>		Carbonite; Tests with —. Beyling	260
Caoutchouc; Chemistry of —. Hinrichsen and others	843	Carbonophosphates in milk and their decomposition. Barillé	957
Cultivation, extraction, and preparation of —. Frank	152	Carborundum. Baradue-Muller	94
<i>See also Rubber.</i>		Carboxylic acids; Manufacture of negatively substituted aromatic — from the aldehydes. (P) Badische Anilin und Soda Fabrik	933
Cape Colony; Manganese ore discovery in —	368	Carboys; Crate for —. (P) Pinkney	510
Regulations under Fertilisers Act in —	1097	Carburetted water-gas; Manufacture of —. (P) Doherty	237
Report of Inspector of Explosives of — for 1908	961	Carburetted liquids; Composition for improving —. (P) Poulain	467r
<i>Caragana arborecens</i> and its bitter principle. Reeb	1164	materials; Mixing ozone with —. (P) Patin	467
<i>Carapa Guyanensis</i> ; Oil from —. Lewkowitsch	150	Carburising gas; Preparation of —. (P) Machlet	94
Caramel; Detection of — in wine, cognac, and beer. Jäger-schmid	376	Cardboard; Glazing —. (P) Armitage and Ibbetson, Ltd., and others	1061
Carbazole derivatives. Ziersch	1189	Carlina oxide. Semmler and Ascher	813
derivatives and dyestuffs therefrom. (P) Haas	517	Carnic acid. Dimroth	595
derivatives; Manufacture of dyestuffs from —. (P) Cassella und Co.	697	Carnallite deposits of Stassfurt. Emslie	394
Carbide electrodes; Manufacture of —. (P) Blackmore	481	Carnauba wax; Saponification of —. Berg	991
Manufacture of —. (P) Hartenstein and others	1314	Carnegie research scholarships. Iron and Steel Institute	111
Treatment of —. (P) Frank	600	Caro's acid:	
<i>See also Calcium Carbide.</i>		Ahrle	980
Carbides; Manufacture of —:		Willstätter and Hauenstein	653
(P) Catani	522	Synthesis and formula of —. Ahrle	363
(P) Price, and Union Carbide Co.	28	Carpets; Colouring yarn for making —. (P) Bright and Bros., and Oldroyd	1311
Manufacture of — by induction heating. (P) Erlwein and Engelhardt	249	Degreasing and cleaning apparatus for —. (P) Scott	201
Carbite; Report of French Commission des Substances Explosives on —	221	Carrageen moss. Hastaden	422
Carbithio-acids; Preparation of —. (P) Bloch and Höhn	1326	Carrot oil. Richter	1222
Carbohydrates from asparagus; Two new —. Tanret	897	Carthamine. Kametaka and Perkin	1189
Converting — into hydrocarbons. (P) Heinenmann	1157	Cartridge manufacture. Statutory Rules and Orders	1327
Determination of molecular weights of —. Wacker	898		
Molecular and solution volumes of colloidal —. Cross and Bevan	806		
Oxidation of — to oxalic acid by nitric acid. (P) Naumann and others	674		
of plant seeds. Schulze and Godet	1055		
soluble; Rendering —. (P) Boidin, and Soc. Anon.			
Amylo	34r		
of soy. Mitsuda	1059		
Carbon; Adsorption of hydrogen by —. McBain	751		
in aliphatic hydroxy-compounds; Determination of —. Berl and Innes	546		
Amorphous; Apparatus for making — by decomposing hydrocarbons. (P) Machitoff and others	709r		
-black from peat; Production of —. (P) Smith, and National Peat Products Co.	430		
Decolorising properties of amorphous —. Pelet and Mazzoli	1193		

	PAGE
Carvenene, $C_{10}H_{16}$. Semmler	106, 1273
Inversion of — to isocarvenene. Semmler	258
Inversion of — to terpinolene. Semmler	441
Carvoxime; A new —. Deussen and Hahn	441
Caryophyllene from clove oil. Deussen	1165
Cascara sagrada bark; Preparation of a clear, soluble extract from —. (P) Penschuck	161, 1006r
Cascien; Acid and alkali equivalents of —. Robertson	902
Action of methyl iodide on —. Skraup and Krause	956
and its applications. Richardson	137
from buttermilk; Production of —. (P) Reuter	256
in cows' milk; Volumetric determination of —. Hart	1099
Hydrolysis of —, and the acids formed. Engeland	1100
Hydrolysis of — by hydrochloric and sulphuric acids. Skraup and Türk	488
Leucine fraction of —. Levene and Van Slyke	1100
Manufacture of —:	
(P) Baechler	489r
(P) Soncini, and Soc. Esportaz. Polenghi Lombardo	36r
in milk; Determination of —. Robertson	1218
in milk; Volumetric determination of —. Van Slyke and Bosworth	1267
Treatment of —. (P) Desgeorge and Lebreil	153
Caseinates; Refractive indices of solutions of —. Robertson	902
Cassava starch from Fiji	1265
Castor oil. See under Oils, fatty.	
bean in the Sudan; Experiments in production of —.	1318
plant; Paper pulp from the —. Wulle	850
seed from Fiji	1258
Catalase; Adsorption of — by colloidal protein and by normal lead phosphate. Peters	103
in cows' milk; Presence of a —. Sarthou	1160
of malt. Van Laer	732
Catalysers; Mineral —. Van Laer	732
Catalytic actions of colloidal metals of the platinum group:	
Paal and Gerum	624
Paal and Roth	611
reactions at high temperatures and pressures. Ipatiew	745
Catechin and catechu-tannic acid; Condensation product of —. (P) Geigy	1031
Catechol-tannins. Franke	1151
Catechu-tannic acid; Converting catechin into a —. (P) Osborne and others	328r
Cathode-dish; Graphite —. Turrentine	890
Cattle feeding cakes; Manufacture of sweet —. (P) Fabre	1268
-food; Manufacture of —. (P) Breyer	621
-food from sulphite-cellulose waste lyes; Manufacture of —. (P) Stutzer	1323
Caustic potash. See Potassium hydroxide.	
soda. See Sodium hydroxide.	
Celestine Blue. See under Oxazine dyestuffs.	
Cellobiose and its osone; Behaviour of — towards some enzymes. Fischer and Zemplén	387
Celluloid; Colouring — for photographic screens, &c. (P) Lehner	109
factories in Holland; Amyl acetate for —	913
films; Applying emulsions to — for photography. (P) Soc. Civile des Pellicules Nouvelles	109
Flameless decomposition of —. Panzer	1061
industry in Japan	958
-like masses; Manufacture of —:	
(P) Boehringer und Söhne	1270
(P) Buehstab	1221
(P) Chem. Fabr. Griesheim-Elektron	1163
Manufacture of —. (P) Stevens	381
Non-inflammable —. (P) Clement	1270
Products of explosion and combustion of —. Pisl and Rasenack	1001
substitutes; Manufacture of —. (P) Story	381
substitutes; Non-inflammable —. (P) Assadas	671r
Cellulose; Action of oxalic acid on —. Knecht	700
Action of sulphuric and nitric acids in the nitration of —. Hake and Bell	457, 823
from agaves. Carneiro	384
alkali; Constitution of —. Müller	37
article; Coloured —. (P) Müller, and Rheinische Künsteledefabrik	1001r
from bagasse; Production of —. (P) Cie. Industrial de Cellulose	257
boilers; Apparatus for causing circulation of liquid in —. (P) Morterud	691
compositions; Manufacture of stable —. (P) Rouxville	257
Determination of —. Renker	1260
Determination of — in cuprammonium solutions. Berl and Innes	546
digestion; Causticising soda ash recovered from —. Schacht	324
Electrolytic bleaching of — as compared with bleaching by bleaching powder. Fraass	380
from esparto and other fibrous plants; Manufacture of —. (P) Dubrot and Lockhart	257
factories; Recovery of by-products from soda —. Falk	622
films; Treatment and application of —. (P) Brandenberger	851

	PAGE
Cellulose—cont.	
Lyes; Purification of sulphite- — for use in the tannery. (P) Kumpf-müller	484
Manufacture of —. (P) Hollins and Taylor	1270
Manufacture of artificial fibres from —. (P) Dreaper	1121
Manufacture of plastic masses, films, imitation leather, &c., from —. (P) Meyer	257
material; Manufacture of a —. (P) Cross and Briggs	623r
mills; Volatile by-products of sulphite- —. Bergström and Lagerlind	37
Molecular and solution volumes of —. Cross and Bevan	806
Nitration of —. (P) Crépelle-Fontaine	855
as a polysaccharide. Briggs	340
Preliminary treatment of — for industrial purposes. Berl	380
Preparation of soluble —. (P) Marino	812, 1163r
Preparation of wood — for making filaments and nitrocellulose. (P) Opfermann and others	1270
products from cellulose cuprammonium solutions; Preparation of —. (P) Friedrich	362, 958r
products; Manufacture of resistant, elastic —. (P) Crumière	241r
pulp from bamboo and rice straw. Knösel	671
Purification of —. (P) Whitney, and General Electric Co.	743
Rendering — proof against water, acids, fire, &c. (P) Roberts	602
acid rubber; Product from —. (P) Soc. Franç. de la Viscose	844, 844r
solutions; Manufacture of —:	
(P) Crumière	159r
(P) Friedrich	934, 980r
Strengthening materials composed of —. (P) Eschaler	362, 1121
substitute. (P) Müller, and Rhein. Künsteledefabrik	1001r
Sulphite-; Determination of — liquors in tanning extracts. Procter and Hirst	293
-sulphite liquors; Purification of —. (P) Kumpf-müller	1324
Sulphite-waste liquors; Manufacture of cattle food from —. (P) Stutzer	1323
Sulphite — waste lyes. Kerp and Wöhler	1001
testing in the paper works. Vieweg	623
Theory of the nitration of —. Saposchnikow	747
threads or filaments; Manufacture of —:	
(P) Dreaper	201
(P) Lecour	880
threads, filaments, ribbons, or films; Manufacture of —. (P) Soc. Franç. de la Viscose	241
threads; Manufacture of —. (P) Thiele	137r
threads, ribbons, &c.; Manufacture of —. (P) Friedrich	1246
Cellulose acetate; Manufacture of moulds and matrices of —. (P) Manissadjian	812
acetate; Manufacture of objects from —. (P) Schloss, and Fürst Guido Dounersmark'sche Künstelede n. Acetatwerke	671, 1061r
acetate; Manufacture of sheets or objects of —. (P) Lederer	1270, 1271r
compounds; Manufacture of — in definite shapes. (P) Lederer	1030, 1221r
derivatives from viscose; Manufacture of —. (P) Lillienfeld	257, 958r
esters. Woodbridge	1061
hydrates. Ost and Westhoff	325
hydrates; Chemistry of —. Schwalbe	216
Cement. (P) Jones, and Acme Cement Plaster Co.	426
Behaviour of hydraulic — in sea-water. Gary and Schneider	1250
from blast-furnace slag; Manufacture of —. (P) Metzger	1251
from blast-furnace slags; Manufacture of hydraulic —. (P) Grau	24
Burning —. (P) Eldred and others	940
burning apparatus:	
(P) Doherty, and Combustion Utilities Co.	524

objects: Obtaining coherent conducting deposits on —.	
(P) Heller and Baumgartl	1315
products from aluminous earths: Manufacture of —.	
(P) Von Seemen	205r
products: Kiln for burning —. (P) Renard	601
surfaces: Reproduction of images on —. (P) Ling and	
others	1063, 1063
ware: Gas kiln for firing —. (P) Payne	141
ware: Ovens or kilns for drying or firing —. (P)	
Meakin, Ltd., and Jackson	141
Cereal products. (P) Quine	903
Cereals: Alteration of — by sulphur dioxide. Carteret	
and Carteret	437
Application of the diastases of unmaltd — to prepar-	
ing alcohol and "amé." Tanaka	376
Change in composition of unground — during storage.	
Leavitt and Le Clerc	620
Cooking —. (P) Panpe	156r
Determination of starch in — by the Zeiss immersion	
refractometer. Lalin	617
Treatment of ground —. (P) Waldmeyer	903
Ceresin and paraffin wax: Quantitative separation of —.	
Marcusson and Schuler	648
Cerite earths: Separation of thorium from —. (P)	
Rosenheim and others	1223
Cerium: Determination of — in rocks. Dittrich	110
Separation of — from other cerite earths. Hauser	
and Wirth	1067
Volumetric determination of — in presence of other	
rare earths. Metzger	626
Cerium compounds of phenols: Preparation of —. (P)	
Scherer	1221, 1269r
compounds: Preparation of opaque enamels containing	
— (P) Rickmann und Rappe	92
salts: Preparation of pure —. Neish	625
Ceylon: Rubber production in —	374
Charcoal: Absorption of carbon dioxide by —. Geddes	
Adsorption of gold by —. Brüssow	1009
Adsorption of sugar by animal —. Herzog	1040
Agglomeration of — obtained by distilling olive kernels.	
(P) Las Industrias del Olivo	932
as blast furnace fuel in Ontario. Sweetzer	93
Conversion of peat into small —. (P) Roux	1116
Decolorising action of various forms of —. Knecht	700
Determination of total sulphur in animal —. Selvatici	
Preparation of highly absorbent —. (P) Goldstein	1008
Utilisation of wood — for metallurgy in the blast	
furnace. (P) Soc. des Hauts Fourneaux, Forges,	
et Acieries du Chili	1090
from vinasses: Loss of salts in production of —.	
Bauer	736
Chaulmoogra oil: Pharmaceutical preparation from —.	
(P) Bayer und Co.	1273
Cheddites containing ammonium perchlorate in place of	
potassium chlorate	221
Cheese: Manufacture of —. (P) Raguet	539
Proteolytic changes in the ripening of Camembert —.	
Dox	436
Cheioroline, an alkaloid from wallflower seeds. Schneider	
196, 1164	
Chemical change: Influence of moisture on —. Baker	385
industry of France	547
industry of Germany	547, 678r
industry of Hungary. Bokor	923
industry of Norway	445
industry of Roumania. 1908	923
products: Manufacture of — in grains, flakes, or	
powder. (P) Reif	802, 842r
trade of Japan	964
Chemicals: Tariff commission on —	1068
Chemistry: Education and research in applied —. Meldola	
Evolution in applied —. Witt	920
and the law. Alverstone	921
Chemists: University training of technical —. Donnan	
The University training of industrial —. Heathcote	
171	
Chemistry in its relation to food. Snell	49
Chemotherapeutics: Present position of —. Ehrlich	218
Chestnut wood: Analysis of —. Alsop	484
Chimney with acid-proof lining: Tall	204
China: Matches in —	544
China: Application of metallic coatings to glazed —. (P)	
Sulman and others	523
Gas kiln for firing —. (P) Payne	141
slip: Purification of —. (P) Solon and Campbell	1088
ware of low fusing grade: Manufacture of —. (P)	
Berdel	310
China-clay and china stone: Recovering — from decom-	
posed granite. (P) Gaved	92
Preparation of —:	
(P) Salamon, and Exploration Co.	709
(P) Salamon and others	1130
Purification of —. (P) Salamon and others	885

explosives. Girard and Laroche	192	Composition of —. Barker and Russell	487
Chlorates: "Active" substance in —. Klopstck	80	Ciders: Rate of fermentation of —. Barker	214
Detection and determination of —. Virgili	363	Cinchona alkaloids: Toluene derivatives of —. Kozniowski	1101
Electrolytic preparation of alkali —. (P) Silbermann	96	alkaloids: Oxidation of — to ketones. Rabe	381
Electrolytic production of —. (P) Thiele	96	back: Detritation of quinine in —. Duncan	439
Purification of —. (P) Gartenmeister	21, 930r	bases: Fission of ketones derived from —. Rabe	541
Chlorazide, N_3Cl . Raschig	29	Cinchonamine. Howard and Chick	53
Chloride: Detection and determination of — in presence of bromide and iodide. Cayen	505	Cinchonidine. Howard and Chick	55
Detection of — in presence of complex cyanides and other halides. Böttger	654	Cinematograph films: Glazed paper for use as temporary support in making —. (P) Labbé and Perret	161
Chlorides: Action of — on cast iron. Carulla	508	films: Recovery of the silver and material of the support from old or broken —. (P) Danzer	1327
Electrolysis of —. (P) Marie	1092	films: Manufacture of —. (P) Lumière et ses fils	491, 1007r, 1168
Electrolysis of alkali —. (P) Billitzer	884	films: Non-inflammable —. (P) De Brailles	1064
Electrolytic decomposition of —. (P) Lévy	1125	films: Restoring worn —. (P) Lumière et ses fils	1064
Manufacture of volatile —. (P) Prior	1014	Cinematography: Gelatin film for use in —. (P) Labbé and Perret	162
of organic acids: Manufacture of —. (P) Meister, Lucius, and Brünig	815	Cinnamic acid in foods: Detection of —. Bigelow	1160
Chlorinated compounds: Production of —. (P) Aylsworth, and Fireproof Products Co.	360	Cinnamic acids: <i>Alb</i> and <i>iso</i> —. Liebermann	441
Chlorinating organic bodies: Process of —. (P) Ellis and others	360	The isomeric —. Büllmann	441, 625
Chlorine: Apparatus for utilising —. (P) Aylsworth, and Fireproof Products Co.	360	from various sources. Erlenmeyer	959, 960
Deacon process. Von Falckenstein	138	Cinnamic aldehyde and sulphurous acid: Compound of —. Kerp and Wödl	1003
Dehydration of moist —. (P) Sperry	22	Cinnamomum zeylanicum, <i>Loyn</i> : Essential oil of root-bark of —. Pilgrim	258
from gaseous mixtures: Separation of —. (P) Goldschmidt	243, 365r, 709r, 1088r	Circulating liquids, especially in cellulose boilers. (P) Morterud	691
and hydrogen: Influence of gaseous nitrogen oxides on rate of interaction of —. Chapman and MacMahon	1196	Citral: Determination of — in terpenoid essence of lemon. Baci	1164
Manufacture of — and ammonia. (P) Whitehouse	794r	in lemon-grass oil: Determination of —. Baci	39
Manufacture of anhydrous — from moist dilute gases and its application in detinning. Sperry	936	Citric acid fermentation. Herzog and Polotzki	538
prepared from hydrochloric acid and potassium permanganate: Purity of —. Wedekind and Lewis	424	fermentation by <i>Citromyces</i> . Buchner and Wüstenfeld	669
and sulphur: Compounds of —. Beckmann	138	Impurities in —. Buchanan	744
Treatment of liquids or suspensions with —. (P) Düring	835	<i>Citromyces</i> : Citric acid fermentation by —. Buchner and Wüstenfeld	669
Treatment and utilisation of —. (P) Paramore, and Electro-Bleaching Gas Co.	362	Citronellal and sulphurous acid: Compound of —. Kerp and Wödl	1003
Chlorobenzaldehydes: Separation of <i>o</i> - and <i>p</i> -. (P) Meister, Lucius, and Brünig	108r	end-citronellal acetate and its conversion into isopulegol. Semmler	744
Chlorobenzyl alcohols: Separation of <i>o</i> - and <i>p</i> -. (P) Meister, Lucius, and Brünig	1226	Classifiers for materials of different specific gravities. (P) Churchill	510
Chloroform, ether, phenol, &c.: Mutual solubility effect of Fühner	141	Clay: Colloid chemistry in relation to —. Alexander	281
Preparation of solidified —. (P) Schleich	814	Effect of preliminary heat treatment on —. Bleininger	1128
Chlorophenols: Identification of —. Denicks	327	Liquefaction of — by alkalis. Fötcher	523
Chlorotoluene sulphonic chlorides: Manufacture of di- and tri-. (P) Geigy	815	Liquefaction of — by alkalis, and use of fluid clay casting in the ceramic industry. Weber	835
Chlorotoluene sulphonic acid and azo dyestuffs therefrom. (P) Badische Anilin und Soda Fabrik	832	Manufacture of slip from —. (P) Weber	1314
Chloroxyonine from East Indian satinwood. Auld	624	Marly — as fluxing material for easily fired bodies. Burd	1128
Chocolate: Composition and analysis of —. Booth and others	629	press: Reuse of water from the —. Gray	1127
Oxalic acid in —. Albury	738	Rendring — plastic. (P) Keppeler and Spangenberg	92
Cholera vibrio: Vitality of — in artificially infected water of Thames, Lee, and New River. Houston	810	Treatment of —. (P) Keppeler and Spangenberg	311r
Cholesterol: Manufacture of — together with lecithin and a fatty oil. (P) Fischer	675r	ware: Preventing efflorescence on —. (P) Henschke and Nemet	524
Occurrence and distribution of — and allied bodies in the animal kingdom. Doré	373	Clays. Rohland	983
Cholesterol α -bromosuccinate: Preparation of —. (P) Chem. Werke vorm. H. Byk	1223	Action of electrolytes on the colloidal substances of —. Rohland	92
Christmas Island: Phosphate exports from —. 375		Absorption by —. Rohland	546
Chromammonite: Tests with reinforced —. Beyling	260	Colloidal substances in —. Rohland	884, 1250
Chromates as colouring matters for paper. Skark	850	Determination of colloids in —. Endell	1250
Manufacture of —. (P) Gibbs	210r	Determination of physical properties of —. Sokoloff	1131
Chronic acid: Determination of — in presence of vanillic acid and iron. Edgar	201	Cleaning apparatus for fabrics, yarns, carpets, &c. (P) Scott	201
Chronic oxide: Red colloidal solution of —. Wondstra	834	fabrics: Rotary machine for —. (P) Teeza Dampf-Fabr. chem. Reinigung u. Kunst-Färberei	471
Solubility of —. Jovitschitsch	242	textiles: Improvements in —. Farrell	19
Chromium and its alloys: Action of carbon monoxide on —. Charpy	368	Chick: For making Portland cement: Manufacture of —. (P) Allan	245, 245r
Determination of — volumetrically. Károvcson and Vlahuta	918	Cloth: Apparatus for treating —. (P) Gantt	307r
Determination of — volumetrically in presence of copper and iron. Hibbert	190	Manufacture of waterproof and lustrous —. (P) Bübner and Riley and Co.	520
mineral in Serbia: New —. Jovitschitsch	246	Manufacture of waxed —. (P) Gebr. Siebert	598
ores: Production of — in the United States	836	Clove oil. <i>See under Oils, essential.</i>	
Passivity of — in acid solution. Alvares	371	Cloves: Determination of essential oil and eugenol in —. Reich	1165
		Clinopodonic acid in dab and green turtle oils: Occurrence of —. Tsujimoto	316
		Coal: Action of air and of oxidising agents on —. Boudouard	195

Producer: Enriching — in carbon monoxide: (P) Trachsler and Ernst	830, 1241r
Producer: Manufacture of —:	
(P) Crossley and Rigby	831r
(P) Panek	302
(P) Slick	592
(P) Smith	877
Producer — plant: (P) Blakeley	196
producer plant:	
(P) King and Workman	466
(P) Soc. Métallurgique de la Madeleine-lez-Lille	930
producer plant especially for recovering ammonia: (P) Crossley and Rigby	930, 1026
Producer: Plant for recovering ammonia from — (P) Lyman	513
producer practice: Anthracite — Stone	10
Producer: Purification of — (P) Chevalet	973
Producer: Purifying and recovering tar from — (P) Neilson	1079
producers:	
(P) Akerlund	787
(P) Bêchevot	1027, 1027r
(P) Beuler	788
(P) Blanchard	513
(P) Bone and Wheeler	693
(P) Bouvier	82
(P) Bowmer	196
(P) Burger, and Thompson and Sons	788
(P) Castel	513
(P) Chapman	930
(P) Chavanne	973r
(P) Duff, and Gas Power and By-Products Co.	930
(P) Dresdner Gasmotorenfabr. vorm. Hille	1027
(P) Fiehet and Heurtey	1117
(P) Fildling	512
(P) Golbe	1187
(P) Hutton	303r, 788r
(P) Jabs	406
(P) Jones, and Kynoch, Ltd.	81
(P) Küppers	930
(P) Lawrenz	302
(P) Lea, and Westinghouse Machine Co.	1079
(P) Lefebvre	513
(P) Lucke	359
(P) McDonough and Conway	877
(P) Maly	82, 360r
(P) Montaland-Davray	302
(P) Morgan Construction Co.	1187
(P) Morton	931r, 1241r
(P) Roche	1116
(P) Schmidt	131, 196
(P) Smltman	131
(P) Soc. Anon. des Houillères de Montrambert et de la Béraudière	1240
(P) Soc. Genevoise pour la Construction d'Instruments de Physique et de Mécanique	1241
(P) Stewart and Stewart	196
(P) Straub, and Power and Mining Machinery Co.	131
(P) Trump	83r
(P) Tully	1240, 1240r
(P) Vater	466
(P) Versen	972
producers for destroying refuse and gasifying fuels: (P) Sepulchre	1187
producers: Generator for use with suction — (P) Farnham	831r
producers: Grates of —:	
(P) Bone and Wheeler	1026
(P) Smith	877

	PAGE
Gas— <i>cont.</i>	
producers for heating gas retorts, &c. (P) Parsy	131, 513
producers; Influence of steam and of loss of heat on efficiency of — Voigt	875
producers for making gas free from tar. (P) Bontillier et Cie.	930
producers for moist fuels. (P) Fintsch A.-G.	647
producers; Portable — (P) Smith	237
producers; Rotary grate for —	
(P) Gutehoffnungshütte, Akt.-Ver. f. Bergbau u. Hüttenbetrieb	1116
(P) Rehmann	1188r
producers; Suction — (P) Berry	876
producers; Suction — for bituminous fuel. (P) Herold	788
producers for use in the manufacture of steel. (P) Seoby-Smith	359
producers; Water vessels or vaporisers for — (P) Ries	196
producing apparatus (P) Marconnet	16r
producing plant. (P) Bickerton and Robson	514r
producing plant; Washers or purifiers for — (P) Temple	1188
production of the United States. Parker	1025
Purification of — (P) Hall, and Security Savings and Trust Co.	237
Purification of coal — (P) McWatters	830
purifiers:	
(P) Edison, and Edison Portland Cement Co.	973
(P) Flössel	788r
(P) Lea, and Westinghouse Machine Co.	1080
(P) Milbourne	1241
purifying apparatus:	
(P) Chandler	1308
(P) Schmidt	1027
reactions; Sudden cooling of hot gases in — (P) Kunheim and Co.	243
Recovery of ammonia from coal — (P) Collins	1027
Removal of carbon bisulphide from coal —:	
Matwin	829
(P) Mayer and Fehlmann	830, 1117r
Removal of naphthalene from —, Ritten	878
Rendering coal — transportable. (P) Menz	1188r
retort furnaces. (P) Ries	788r
Retort furnaces for making — (P) Thom and Pryor	1125
Retort furnaces for making illuminating — (P) Bolz	82, 514r
retorts:	
(P) Dempster and Sons, Ltd., and Brooke	647, 593r
(P) Gennotte	593r
(P) Rindon	693
retorts; Distillation in vertical —, Rueb	875
retorts; Glover and West vertical — at St. Helens, Colman	829, 1115
retorts; Producer for heating — (P) Parsy	131
scrubbers or purifiers. (P) Farnham	1117
scrubbing apparatus. (P) Nix	1079
Suction; Home Office Memorandum as to use of — in factories	79
from tar; Manufacture of — (P) Rincker and Wolter	648r
testing	1186
testing burner for producer-gas plants. (P) Hiller and others	931
Utilisation of coke-oven —, Cuvelette	79
washer. (P) Wilton	972
Washer or cooler for freeing — from tar or dust. (P) Burstall	514
Washer-scrubbers for purifying coal — (P) Kirkham, Hulett, and Chandler, Ltd., and Hersey	83, 1080r
washing apparatus:	
(P) Ensign	1079
(P) Feld	1239, 1308r
Water — apparatus. (P) Carroll and others	648r
Water; Apparatus for making — (P) Smith	876
Water — generator. (P) McKay and Cheney	237, 973r
Water; Home Office Memorandum as to use of — in factories	79
Water; Manufacture of —:	
(P) Glasgow	1116
(P) White	1079
Water; Manufacture of carburetted — (P) Doherty	237
Water; Production of — in vertical retorts:	
Körting and Geipert	79
Strache	79
Water; Scrubbing, cooling, &c. — (P) McIlhenny	83
from wood; Manufacture of — (P) Loomis and others	831r
Gaseous bodies; Mixing, measuring, and carburetting — (P) Bouvier	788r
bodies; Separating suspended particles from — (P) Cottrell	416r
ions; Apparatus for producing — (P) Blake	370
mixtures; Apparatus for measuring and indicating explosive and calorific values of — (P) Evans	627
mixtures; Reactions in — under great pressures. Briner and Wroczynski	705
mixtures; Separating constituents of — (P) Mazza	1307r
Gases; Apparatus for analysis of —:	
(P) Caldwell	110
(P) Rodhe	1065, 1168r
Apparatus for dissolving — in liquids. (P) Hommel, and Metals Extraction Corporation	77

	PAGE
Gases— <i>cont.</i>	
Apparatus for extracting tar, dust, &c., from — (P) Burstall	514
Apparatus for generating — by electric discharges in air. (P) Mitchell	989
Apparatus for introducing — into liquids. (P) Wenström	356
Apparatus for preparing rare — from gaseous mixtures. Heinrich	1125
Apparatus for purifying — (P) Sepulchre	973r
Apparatus for purifying and cooling — (P) Uhlmann	359
Apparatus for separating — (P) Honigsmann	829
Apparatus for separating mixed — (P) Fiesse	1023
Apparatus for subjecting — to the action of liquids. (P) Fowler and Medley	972r
Apparatus for treating — (P) Wolf	132
Apparatus for treating — electrically:	
(P) Bridge	1144
(P) Mosicki	989
Apparatus for treating — with liquids. (P) Feld	1239
Centrifugal apparatus for purifying blast furnace and other — (P) Soc. Anon. J. Cockerill	16r
Centrifugal separator for removing solids or liquids from — (P) Michaelis	1114
Chemically combining — (P) Lovejoy and Bradley	28
Cleaning — (P) Ernst	1188r
Compressing — (P) Humphrey	300r, 784
Compressors for —	929
Controlling or deflecting the flow of flue and other —, for CO ₂ recorders. (P) Carr	1117
Determining the calorific power of combustible —:	
(P) Poulenc freres, and Lemoult	817
(P) Schönberg-r	261r
of dry distillation; Purifying and obtaining by-products from — (P) Burkheiser	359, 1117r, 1188r
Effecting chemical action in — (P) Lovejoy and Bradley	28
Electric furnace for treating — (P) Salpetersäure Ind.-Ges.	715, 1046r
Extraction of ammonium sulphate from distillation — (P) Gewerkschaft der Steinkohlensche Mont Cenis	1308
Extraction of sulphur, &c., from furnace — (P) Carpenter, and Amer. Iron and Steel Alloys Co.	704
Filtering — (P) Winter	465
Filtering and purifying — (P) Jaubert	299
Flameless combustion of —, Meunier	195
Ignition temperatures of —, Dixon and Coward	301
Influence of colloids and colloidal suspensions on the solubility of — in water. Findlay and Creighton	750
Liquefaction of —:	
(P) Bobrick	982r
(P) U.S. Liquid Air and Oxygen Co.	939, 939r, 982
liquefied; Storage vessel for — (P) Groth	1185
and liquids; Apparatus for effecting reactions between — (P) Bourdon	1078
and liquids; Apparatus for effecting intimate contact between — (P) Kirkham, Hulett, and Chandler, Ltd., and others	873
and liquids; Apparatus for separating — (P) Malmendier and Stühler	785
and liquids; Apparatus for simultaneously treating — (P) Steynis	691r, 742r
Making and mixing — and delivering the mixed gas to gas engines. (P) Loomis and others	302
Mixing ozone with — for illumination and power. (P) Patin	467
Obtaining by-products from — (P) Hilgenstock occluded in the lavas from Mont Pelée and Vesuvius. Grossmann	494
occluded in certain metals. Delachanal	368
Preventing decomposition of products in reactions between — (P) Scherbius	1198
Purifying and cooling hot — (P) Soc. Anon. des Hauts Fourneaux, Forges, et Acieries de Pompey	16
Purifying and recovering tar, &c., from — (P) Neilson	1079
Recovery of ammonia from distillation — (P) Act.-Ges. f. Kohlendestillation	516
Recovery of valuable — (P) Perks, and Volatile Solvents Recovery Co.	691
Removing carbon bisulphide from — (P) Mayer and Fehlmann	830, 1117r
Replacing carbon monoxide by hydrogen in — (P) Chem. Fabr. Griesheim-Elektron	1116
Separating liquid and dirt from — (P) Scheer und Co.	510
Separation of — of different densities. (P) Tavernier	365, 835r
Separation of tar from distillation — (P) Otto und Co.	830
from solids; Obtaining — (P) Ridley	884
Sudden cooling of hot — in gas reactions. (P) Kunheim and Co.	243
Systematic separation of combustible —, De Voldere	972
Testing — (P) Arndt	1323
Treating materials with — (P) Haas	828
Treatment of corrosive — (P) U.S. Smelting, Refining, and Mining Co.	799, 988r
Treatment of — electrically. (P) Mosicki	1046r
Washer-scrubbers for purifying — (P) Kirkham, Hulett, and Chandler, Ltd., and Hersey	83
Gelatin; Adsorption compounds and the tanning of —, Lüppo-Cramer	211

	PAGE		PAGE
Gelatin—cont.		Glazes—cont.	
from animal size; Distinguishing wool —. Herz and Barraclough	1193	Production of opalescence in highly acid —. Whitmer	1129
Colour reaction of —. Liesegang	1262	Solubility of metallic oxides in —. Ramsden	474
Composition of —. Skrap and von Biehler	947	Glover tower; Acid-forming capacity of the —. Meyer	1032
Copper as an impurity in —. Hart	739	Glucose in leather; Determination of —. Bennett	947
Determination of traces of chlorides in —. Lüppler-Cramer	1262	Manufacture of —. (P) Duryea	456r
-dynamite; Machine for packing —. (P) Donaldson, and Du Pont Powder Co.	816	See also Dextrose.	
film for cinematography. (P) Labbé and Perret	162	d-Glucose; Biotation of —. Osaka	617
films coated on either side with collodion; Preparation of —. (P) Moh	110	Glucosides, cyanogenetic; Transformation of — during germination. Guignard	38
films; Electrical method of measuring changes in chromatod — on exposure to light. Mayer	442	Hydrolysis of — by emulsion. Fichtenholz	1002
Jelly; Diffusion of chromium, iron, and aluminium salts through —. Procter and Law	297	New member of the saponin-digitalin group of —. Moore and others	1081
Plaited cotton threads for drying —. (P) Manoury et Cie.	153	Glue; Bleaching agent for —. (P) Badische Anilin und Soda Fabrik	535
solutions; Purification of —. (P) Spigno	886	Boilers for melting —. (P) Allan and Richmond	974
Sulphurous acid in commercial —. Lange	993	Manufacture of colourless —. (P) Lehmann 897, 1152r	
Gelatinous substances; Formation of oxalic acid from —. Sadikow	1097	Plaited cotton threads for drying —. (P) Manoury et Cie.	153
Gelatoid thermoplastic compound. (P) Goldsmith	804	Preparation and application of —. (P) Gillet	1263
Gelose; Manufacture of —. (P) De la Guéronnière	999	from rabbit skins; Manufacture of dry —. (P) Bonney et Winder	1213
German East Africa; Rubber samples from —	945	solutions; Manufacture of — free from fat. (P) Act.-Maschinenbau-Anst. vorm. Venueth and Ellenberger	897
German-silver; Preparation of — from metal mixtures containing iron. (P) Elektra-Stahl Ges. m. b. H.	801, 801	solutions; Purification of —. (P) Spigno	896
Germany; Cement industry of —	885	solutions; Separation of fat from —. (P) Meyer	971
Chemical industries in —. 547, 678, 1010, 1226		tester. (P) Smith	252
Coal industry of — in 1907-8. Bertelsmann	511	Gluten; Physical state of —. Wood and Hardy	378
Customs Tariff modifications in —	965	in wheat flour; Determination of dry —. Rammstedt	156
Development of the iron industry in —. Wüst	602	from wheat flour; Manufacture of —. (P) Klopfer	999r
Dyestuff industry of — and the new American Tariff	933	Glycerides of hydroxychloro-fatty acids; Preparation of —. (P) Cons. f. Elektrochem. Ind. and Imbert	945
Mineral production of — in 1908	446	Mixed — in natural fats. Klimont and Meisels	662
Paper industry of — in 1908	811	of palmitic and stearic acids; Mixed — in mutton tallow. Bömer	482
Portland cement trade of —	1132	Glycerin	719
and the United States; Patent treaty between —	922	Distillation of —. (P) Wood, and Marx and Rawolle	200
Geslilt 1 and 2; Tests with —. Beyling	260	Use of the viscous liquids obtained by heating —. (P) Claessen	30r
Glass; Action of oxidising and reducing gases on the colours of —. Hermann	425	Glycerol; Electrolysis of —. Löb and Pulvermacher	617
annealing furnaces or ovens. (P) Rembaux	1249	esters; Nitro derivatives of —. Paternò and Benelli	1168
Annealing and hardening —. (P) Farling	940	esters; Preparation of mixed —. (P) Vender	675
Apparatus for drawing —. (P) Window Glass Machine Co.	23r, 23r, 425, 795r	Manufacture of polyglycerins from —. (P) Claessen	30r
Apparatus for making —. (P) Sievert	983	Sensitive reactions for detecting and identifying —. Denigès	372
Apparatus for making sheet —. (P) Oppermann	425r	Glycerophosphate of lime. U.S. Customs decision	382
articles; Fire-glazing or finishing —. (P) Cummins and Schwenzfeier	22, 475r	Glycol; Electrolysis of —. Löb and Pulvermacher	617
Continuous apparatus for making sheet —. (P) Rowart	785	Glycolic acid; Delicate reaction for —. Denigès	744
Cutting — by means of an electric wire. Jouard	657	Preparation of — by electrolytic reduction of oxalic acid. (P) Deuts. Gold- und Silber-Scheide Anst.	108
Drawing —. (P) Window Glass Machine Co.	425, 475r, 795r	Glycyrrhizic acid; Occurrence of —. Tschireh and Gauchmann	1002
Effects of alumina on —. Frink	1127	Glyoxylic acid, esters, and amide; Preparation of — from oxalic acid. (P) Kitzberger and Co.	815
Electric furnace for continuous manufacture of —. (P) Sauvageon	1130, 1200	Goffering effects on yarns, tissues, &c.; Production of —. (P) Tredup	520
furnace. (P) Royer	141, 1088r	Gold; Adsorption of — by charcoal from solutions. Brissow	1040
Furnace for melting —. (P) Mount and Pfleger	27r	alloys or bullion; Electrolytic parting of —. (P) Norddents. Affinerie A.-G.	482, 840r, 1047r
heating and drawing furnace. (P) Houze	1130	amalgam; Apparatus for distilling mercury from —. (P) Bennett	1204
Hermetically sealing a conductor into —. (P) Bastian and Calvert	97r	bullion; Determination of silver in —. Taylor	367
Home Office Regulations for vitreous enamelling of — machine and process. (P) Heintz	141	cyaniding of sand; Use of the vacuum pump in —. Caldecott	367
machines; Continuous, vacuum, window —. (P) Hershey	23, 311r	Determination of — in copper bullion. Hunt	368
making; Tank furnace for —. (P) Rembaux 795, 1036r		Electrochemistry of the solution of — in potassium cyanide. Ekeley and Tatum	478
Manufacture of borie acid —. (P) Ackermann	1034	Extraction of —. (P) Seigle	428r
Manufacture of plate —. Knoblauch	91	Extraction of — from cyanide solutions and regeneration of the cyanide. (P) De Wilde	479
Permeability of — to gases. Stock and Heynemann	657	Extraction of — from its ores. (P) Sébillot and Maublanc	427
plates; Gas-kiln for bending large —. (P) Payne	141	extraction in Rhodesia. Cooke	142
plates; Manufacture of —. (P) Sievert	601, 795	Extraction of — from slimes. (P) Crosse	370, 988r
Production of chromated glue images on —. (P) Hans	1006, 1064r	-lead bullion; Cupellation of —. Melville	143
Production of mosaic —. Parkert	1249	Manufacture of leaf —. (P) Kurz	608, 840r
Quartz; Melting and working —. (P) Mehner	1035	-magnesium alloys. Vogel	1041
Reproduction of images on —. (P) Ling and others	1063, 1063	ores; Assaying —. (P) Hames	470
sheets; Apparatus for making —. (P) Wadsworth, and Pressed Prism Plate Glass Co.	92	ores; Cyanide lixiviation of — by agitation. Brodie	478
sheets; Manufacture of —. (P) Itchecock and Brown	522	precipitates and bullion; Smelting — with oil fuel. Yates	1040
silicates of the porcelain type; Determination of melting points of —. Barrett	1129	Precipitation of — from cyanide solutions. Caldecott	658
surfaces; Mirroring —. (P) Chem. Fabr. von Heyden	23r	precipitation from cyanide solutions by zinc. Clark	367
surfaces; Silvering —. (P) Chem. Fabr. von Heyden	92r	Precipitation of — from solutions. (P) Hay and Tennent	942
tubing; Bursting strength of —. Roebuck	983	production of the Federated Malay States	986
Utilisation of rocks in making bottle —. Plenske	244	production of the United States	1316
works; Furnaces for —. (P) Garros	310	Recovery of — by the cyanide process. (P) Strange and others	206
Glasses; Formation of —. Cobb	657	Recovery of — from solutions. (P) Riedel	608
Relation between refractive index and density of —. Larsen	1035	-silver alloys. (P) Craft and others	1204
Glazes; Colorimetric test for lead in —. Factory Inspector's Report	752	and tellurium; Fusibility of mixtures of —. Pélabon	606
Determination of melting points of —. Barrett	1129	Gold and bromine; Compounds of —. Meyer	242
Development of copper-red in — in a reducing atmosphere. Franchet	475	chloride; Reaction of — with aluminium. Dauvé	331
Formation of —. Cobb	657	Government Laboratory; Report of Principal Chemist of the —. 1908-9	952
Influence of fluorine in hard-fired —. Vogt	709		
Leadless earthenware —. Schmidt	600		
Matt —. Rhoad	1129		
Peculiar property of some —. Mayer	1129

Grading assays. Yates	426
Grain; Presence of amylase in old —. Brocq-Roussen and Gain	262
Treatment of —. (P) Dombach	1268
Granite, artificial; Manufacture of —. (P) Jakobi	311
Recovering china clay and china stone from decomposed —, and separating the clay, mica, and quartz. (P) Gaved	92
Granulators for molten slag, &c. (P) Warren	1037
Grape musts; Proportions of dextrose and levulose in —. Mestre	668
Graphite articles; Manufacture of —. (P) Williamson, and Internat. Acheson Graphite Co.	1144
discoveries in British African Colonies	981
Formation of — by interaction of magnesium powder and carbonates. Ellis	89
production in the United States	1086
Manufacture of —. (P) Acheson, and Internat. Acheson Graphite Co.	708r
Grasses; Preparing vegetable fibres for spinning from —. (P) Reichmann	1193
Grease; Apparatus for removing — from material to be detinned, &c. (P) London Electron Works Co. and Kardos	714
from coal-tar; Obtaining mineral —. (P) Sauvageot	932
Filters for —. (P) Scurfield	663
from garbage; Extraction of —. (P) Wheelwright	810
from sewage sludge; Recovery of —. Bechhold and Voss	1000
from sewage, waste water, &c.; Apparatus for extracting —. (P) Ges. f. Abwässerklärung	105
Greece; Customs duties on beeswax, mineral oils, &c. in —. 1319	
Green-turtle oil. See under Oils, fatty.	
Grinding colours; Machine for —. (P) Richter	1147
efficiencies. Yates	426
Grosny petroleum; Properties of —. Rakusin	789
Ground-nuts from Fiji	1259
Guaiaacol; Reaction of — with hydrogen peroxide. Denizès	905
Guaiaacol carbonate; Salts of sulpho acids of —. (P) Boehringer Sohn	544r
carbonate sulphonic acid derivative. (P) Einhorn, and Boehringer Sohn	1223r
compounds. (P) Hoffmann-La Roche and Co.	490
Guaiaacol-5-sulphonic acid and its salts; Preparation of —. (P) Hoffmann-La Roche and Co.	1005, 1223
Guaiaicum reaction; The —. Alsberg	44
Guanidine; Preparation of —. (P) Ulpiani	674
Guanine derivatives; Preparation of 8-substituted —. (P) Bayer and Co.	1167
Gum; Extraction of a —. (P) Ephraim	842
-like substance; Manufacture of a — from Java olive oil. (P) Wedemeyer	534
Manufacture of chewing —. (P) Darling	1051
Manufacture of —. (P) Hervey	1157
Manufacture of varnish —. (P) Kessler	720
resins; Purification of —. (P) Johnson	1148
Rubber-like —. (P) Hunicke, and Continental Rubber Co.	995
solution; Preparation of — in gumming paper. Herzfeld	851
Gum benzoin; Siamese —. Reintzer	1148
tragacanth; Distinction of genuine — from spurious Indian gums. Scoville	434
tragasol; Manufacture of —: (P) Castle	153, 848r
(P) Castle, and Gum Tragasol Supply Co.	731r
Gums; Chemistry of the Sudan —. Edie	536
Enzymes in acacia and other —. Reintzer	1056
Purification of —. (P) Johnson	1148
Sudan —	536
Treatment of — with chlorine. (P) Electrolytic Alkali Co., and others	31
Guncotton and its manufacture. Nathan	177
Production and application of —. Nathan	443
Gumpowder. (P) Claessen	384r
Manufacture of —. (P) Trench and Lynn-Smart	676
Smokeless —. (P) Claessen	162r
See also Powder.	
Gurjun balsam oil. Deussen	1165
Guttapercha; Agglomeration and regeneration of —. (P) Rouxeville	665r
Manufacture of pure —. (P) Scholz, and Kautschukges. Schön and Co.	720r
Gypsum; Apparatus for burning — in powder or lumps. (P) Monberg	24
in Nova Scotia	1248

H

Hair, artificial; Manufacture of —: (P) Lecœur	88
(P) Le Crinoid	1194
Dyeing —: Beltzer	934
(P) Meister, Lucius, und Brüning	652, 833

Half-silk; Dyeing — with sulphide dyestuffs. (P) Farbwerk Mühlheim vorm. Leonhardt und Co.	792
Weighting — in hanks or pieces. (P) Müller	471
Half-wool fibres and fabrics; Production of two-colour effects on —. (P) Meister, Lucius, und Brüning	979
Halogenalkyloxy-monocarboxylic acids; Preparation of aromatic —. (P) Chem. Fabr. von Heyden	1063
α -Halogen-isovalerylurea. (P) Saam, and Knoll und Co.	383r
Halogens; Determination of — gravimetrically by means of silver nitrate. Alefeld	163
in organic compounds; Determination of —. Tacon	164
Halphen's reaction for cottonseed oil; Modification of —. Garnier	717
Hardhead; Bessemerising of —. Levy and Ewen	606
Harmaline, a substitute for quinine. Gumm	1324
Hartsalz deposits at Stassfurt. Einsie	395
Hatchettin from Bonarka, near Craew. Morozewicz	419
Hats; Dyeing apparatus for —. (P) Bauer	1311
of straw, palm-leaf, &c.; Manufacture of —. (P) Pearson	905
Hawaii; Cane sugar industry in —. Deerr	725
Vanilla in —. Smith	1002
Hazel leaves; Oil of —. Haensel	542
Heater; Vacuum —. (P) Dunn and Dunn	15r
Heating bodies containing zirconium for electric heaters. (P) General Electric Co.	83
Electrical process of —. (P) Johnson, and Continuous Zinc Furnace Co.	1296
liquids; Apparatus for —: (P) Brücke	79
(P) Marchant	510
materials; Process of —. (P) Williams	799, 799r
Construction of —. Snero-Filterwerk, Snero und Co.	691, 1186r
for liquids or gases. (P) Tixier	591
materials by using the heat of combination of sulphur and other bodies. (P) Lang	590, 1186r
power of gas; Determination of the —. Techn	358
by radiation; Refractory mantles for the —. (P) Delage	130
<i>Helianthus</i> tubers as material for the production of spirit. Kocks	487
Hemp; Cynotoxin in Canadian —. Finemore	325
fibres; Proofing —. (P) Lainville	882
Manila and Sisal — from India	651
Mauritius	978
Sisal; Composition and utilisation of pulpy waste from the stripping of —. Hébert and Heim	421
Sisal — from East Africa, Uganda, and Nyasaland	978
Hempel gas-burette; Modification of the —. Spencer	676
Hembane; Constituents of Java —. Watanabe	744
<i>Herba Scopolia japonica</i> ; Constituents of —. Dieterich	745
Herring-guano; Availability of phosphoric acid in —. Mitsuta	1054
Heusler's magnetic alloy. Jack and Ross	246
Hexabromindigo; Manufacture of greenish-blue —. (P) Meister, Lucius, und Brüning	1245
Hexamethylenetetramine and mercuric salts; Soluble compounds of —. (P) Busch	383r, 1006r
Hexose-phosphate formed by yeast juice from hexose and phosphate. Young	1322
Hexoses; β -Hydroxy- α -methylfurfural as the cause of some colour reactions of —. Van Ekenstein and Blanksma	536
Hide powder; Estimation of swelling action of acids on —. Stiasny	946
powder; Rapid determination of acidity of —. Hough	804
powder; Zeuthen's method for washing —. Paessler	1097
substance; Determination of dissolved — in soak liquors and lime liquors. Bennett	291
substance in leathers; Determination of —. Bennett	291
Hides; Degreasing —. (P) Deroy	211
The interfibrillar substance of animal —. Van Lier	1150
Machine for treating —: (P) Slecomb	1263
(P) Turner Co.	721
Manufacture of material of the nature of leather from —. (P) Reddan	665
Preparation of — for making leather. (P) Leconte	212r
Removing oil and lime from, and disinfecting —. (P) Lehmann	1151
Tanning —. (P) Schmid, and Boehringer Sohn	1212
Tanning and treating —. (P) Robeson	1052, 1052
Tanning ungrained —. (P) Soc. Anon. des Mat. Tannantes et Colorantes	804, 996
Treatment of —: (P) Nance	101, 432r
(P) Vidal	432r, 1262
Treatment of tanned —. (P) Spigno	721

Iron—cont.	
Magnesium-iron alloy suitable for deoxidising cast — (P) Chem. Fabr. Griesheim-Elektron.....	480
Malleable cast — Namias	1252
Manufacture of — : (P) Ellis	247
(P) Jones	27r, 799r
Manufacture of — by the basic Bessemer process, (P) Flohr and others.....	609r
Manufacture of malleable cast — Giolitti.....	205
Manufacture of pig — in the electric furnace from pyrites residue, Carcano	477
Manufacture of — in relation to other industries, Harbord	867
Manufacture of steel from chromiferous pig — (P) Carney	145r
Manufacture of malleable — from cast iron rich in silica and phosphorus, (P) Massenez.....	25
Melting — in a foundry cupola, McCormack.....	1133
Melting and refining — (P) Johnson.....	1255
Metallurgical furnaces for — (P) McCarty.....	660r
Metallurgy of — (P) Simpson and Oviatt	527, 943r
ores; Arbitration analysis of	1040
ores; Briquetting finely divided — (P) Schumacher	798
ores; Electric furnace reduction of — Richards.....	716
ores; Increasing the reducibility of spathic — (P) Cöln-Müsener Bergwerks-Akt.-Ver.	1204
ores and ironstone shale; Apparatus for heating — (P) Peat	660
ores of Ontario, Willmott.....	93
ores; Reduction of — : (P) Fogler and others.....	145
(P) Jones	660r
ores; Smelting — (P) Kendall and others.....	248r
ores; Smelting chrome — in a blast furnace, Monnartz	367
ores; Treatment of — : (P) Jones	370r
(P) Jones, and Jones Step-Process Co.....	1140
(P) Morgan	247
ores; Treatment of silicious — (P) Bertolus.....	149
ores; Treatment of titaniferous — : (P) Borchers	986, 1316r
(P) Sindig-Larsen	207r
oxide scale; Removing — electrolytically, (P) Danforth and Jones.....	1317
oxides; Smelting — (P) Lash.....	799r
Passivity of —, Krassa	838
Passivity of — in acid solution, Alvares.....	371
Peroxidation of — in copper blast furnaces, Rizzo	985
Patron	885
in pottery materials; Determination of —, Hadank	885
Preparation of — for casting : (P) Chem. Fabr. Griesheim Elektron.....	480, 1143r
(P) Rakowicz and others.....	987r
Preparation of malleable cast —, Giolitti, Carnevali, and Gherardi.....	245
Preservation of —, Cushman	605
Production of pig — in the electric furnace at Domnarvett, Sweden, Neumann.....	1257
Quantitative precipitation of —, Schirm	1008
Reducing the carbon content of cast — (P) Schiessl	145
Refining — : (P) Reid	609, 1045r
(P) Sejournet, and Soc. Electrometall. Franc.....	1140
Retardation of oxidation of — by chromium trichloride, Rohland	1315
Rusting of —, Moody	245
Separation of — from chromium, aluminium, and zinc, Pozzi-Escot	677
Separation of graphite in white cast — heated in water under pressure, Charpy	796
Smelting and refining — (P) McCarty.....	660r
Soldering cast — with metals or alloys, (P) Fano fu Gustavo, and Voghera.....	480
Solution for treating — (P) Saunty Metals Co. 145, and Steel Institute; Carnegie research scholarship of the	111
Tempering and re-heating — Maurer.....	245
Test for hardness of —, Turner	625
Tests for the action of chlorides on cast —, Carulla, from tin-plate scrap; Preparation of merchantable —, (P) Sperry	369
Tin-plating — (P) Hollis.....	429
Transformation of —, Gruef	837
Treatment of — (P) McCarty.....	314r
Treatment of foundry — (P) Custer and others.....	889
Treatment of — to prevent oxidation or rust, (P) Rudge-Whitworth, Ltd., and Heathcote	206
Treatment of — to prevent rusting, (P) Coslett and others.....	986
waste; Converting — into cast steel, (P) Soc. Anon. des Acières de France.....	986

Mortar— <i>cont.</i>	
Rendering — waterproof. (P) Kathe.....	602, 940r
Treatment of bitumen for making —. (P) D'Olivier-Mansau.....	602
Mortars; Decomposition of — by sulphate solutions. Bied.....	711
Mosaic glass; Production of —. Parkert.....	1249
Motor-cars; Steel for —. Holden.....	312
Motors; Deodorising exhaust gases in —. Frenkel.....	692
Mont Pelée; Gases occluded in the lava from —. Grossmann.....	494
Mucic acid; Oxidation of — in presence of iron. Petrabosch.....	725
Mull; Coal in —.....	874
Multicoloured surfaces; Preparing — by direct dyeing. (P) Verein. Kunstseidefabr.....	329, 627r
Murex brandaris; Dyestuff of the antique purple from —. Friedländer.....	361
Muslins; Weighting process for —. (P) Durand.....	307
Mists; Apparatus for desulphiting and concentrating —. (P) Sicard and Vidal.....	1217
Mutton tallow; Mixed glycerides of palmitic and stearic acids in —. Bömer.....	482
Myliobates aquila; Fish-liver oil from —. Huwart.....	842
Myrobalans; Chebulic —. Hooper.....	1151
Extraction of —. Eitner.....	101
Myroxylon balsamum var. J. punctatum; Quino-quinio balsam from —. Hallwich and Jama.....	1271
Myrrh; Therapeutic agent from —. (P) Von Bolton.....	854

N

Naphtha; Constituents of solvent —. Schultz and Perl.....	1188
Naphthalene and formaldehyde; Preparation of condensation products from —. (P) Badische Anilin und Soda Fabrik.....	431
in gas; Determination of — and its removal. Rütten in making rubber goods; Use of —. (P) Rutgerswerke A.-G.....	875
picrate and the determination of naphthalene. Jorissen and Rütten.....	100
Preparation of β -halogen derivatives of —. Darzens and Berger.....	1179
Sulphonation of —. Ewies.....	419
Naphthalene derivatives; Action of sulphites on some 1,5 hydroxy and amino —. Bucherer and Uhlmann.....	931
Naphthantraquinone; Manufacture of pigments or lakes from —. (P) Badische Anilin und Soda Fabrik.....	1081
α -Naphthol; Reaction for —. Dané.....	532, 1050r
Naphthol Yellow S. See under Azo dyestuffs.	219
α -Naphtholarsinic acid; Preparation of —. (P) Adler.....	220
1,8-Naphthylenediamine; Manufacture of condensation products from —. (P) Bayer and Co.....	470r
β -Naphthylindigo; Bromo-derivatives of —. (P) Meister, Lucius, and Brüning.....	832r, 977r
Naphthylpyrazolonesulphonic acid. (P) Bayer and Co.....	198r
Narcine. Freund and Oppenheim.....	541
Narcotine; Reactions for —. Labat.....	813, 813
Natal; Whale oil industry of —.....	944
Nepheline as source of potassium for plants. Prianichnikov.....	722
Nerol; Extraction of — from <i>Helichrysum</i> oils. (P) Helne and Co.....	220
Netherlands customs decisions.....	922
customs tariff; Proposed increase of —.....	1328
Duty-free admission of certain chemicals into the —.....	1002
Exemption from excise duty of salt for use in zinc chloride factories in the —.....	1313
Neuralgine; Distinguishing — from pyramidone and antipyrine. Monferrino.....	852
New Brunswick; Shale deposits of —.....	879
Shales of —. Baskerville.....	878
New Guinea; Rubber industry of —.....	1261
New River water; Examination of — for typhoid bacillus. Houston.....	104
New South Wales; Bismuth in —.....	1042
Mineral production of —.....	941
Pure Food Act in —.....	902, 908, 1059
New Zealand Meat Freezing Works; Chemical control in the —. Wright.....	124
Nickel; Absorption of hydrogen by —. Sieverts and Hagenacker.....	246
and its alloys; Action of carbon monoxide on —. Charpy.....	368
and its alloys; Manufacture of — from garnierite. (P) Roux and others.....	990
coatings; Removing electrolytic —. (P) Levy.....	148
and cobalt; Separation of —. Grossmann.....	1169
coins; Analysis of —. Van Heteren and Van der Waerden.....	444
copper alloys; Manufacture of —. (P) Browne, and Canadian Copper Co.....	1092

Nickel— <i>cont.</i>	
copper mattes; Treatment of —. (P) Carriek and Pattison.....	236, 1256r
crucible for the determination of carbon in steel. Ruppel.....	384
Determination of — in presence of cobalt. Sanchez.....	749
Determination of — volumetrically. Baccovecu and Vlahuta.....	918
Electrochemical behaviour of —. Schweitzer.....	989
Electrolytic determination of —. Schumann.....	43
Extraction of — from silicious ores: (P) Chalas.....	207r, 481r
(P) Price, and Central Trust Co.....	140
Manufacture of —. (P) Browne, and Canadian Copper Co.....	1092
Manufacture of pure —. (P) Soc. Electrometall. Franc.....	1090
ores; Treatment of —. (P) Betts.....	601
Separation of — from cobalt. Pritze.....	818
Separation of — from iron. Hassreidter.....	918
in steels; Determination of — by Brinck's, Grossmann's, and the electrolytic methods. Prettnier.....	525
Treatment of magnetic pyrites containing —. Warlimont.....	313
Nickel oxide; Action of carbon monoxide on —. Charpy.....	368
sulphide; Separation of — from aqueous solutions. Thiel and Ohl.....	308
Nicotine; Determination of —. Bertrand and Javillier.....	326
Determination of — in concentrated tobacco juice. Porchet and Régis.....	1220
Nicotine silicotungstate. Bertrand and Javillier.....	326
Nigeria; Cotton from —.....	978
Indigo products from Northern —. Perkin.....	353
Rubbers from Southern —.....	1260
Nightsoil; Apparatus for reducing and recovering ammonia from —. (P) Frykkind.....	810
Nigrisin; Production of — on the fibre. Brandt and Federmann.....	1121
Niobic acid; Determination of —. Weiss and Landecker.....	1109
Niobium; Determination of — in presence of tantalum. Taylor.....	818
Determination of — and its separation from silica. Von John.....	1089
p -Nitraniline Red. See under Azo dyestuffs.	
Nitrate works; Hydro-electric — at Notodden.....	1214
Nitrates; Apparatus for making —. (P) Kettler.....	473
Catalytic determination of — in soil solutions. Syme.....	375
Conversion of nitrites into —. (P) Badische Anilin und Soda Fabrik.....	884
Decomposition of — by micro-organisms. Franzen and Löhmann.....	1323
Detection of small quantities of — in presence of bromides. Villédieu.....	834
Determination of —. Zeller.....	856
Determination of — by cinchonamine. Howard and Chick.....	53
Determination of small quantities of —. Farcy.....	849
Electrical production of —. (P) Bunet and Badin.....	1198
Loss of — during drying of plants. Couperot.....	219
Manufacture of —. (P) Hempel.....	981
Manufacture of — from air by the Birkeland-Eyde process. Eyde.....	1214
Manufacture of artificial — for fertilising. (P) Montbaron and Ducommun-Müller.....	1098
Manufacture of — from air in Germany.....	936
Manufacture of solid — from nitrous gases. (P) Badische Anilin und Soda Fabrik.....	650
and nitrites; Formation of mixed crystals of alkali —. Bruni and Mengheni.....	1123
in water containing chlorides; Determination of —. Mareille.....	957
Nitric acid from air; Manufacture of — in Austria. Russ.....	882
Apparatus for making —. (P) Kettler.....	473
Apparatus for making dilute —. (P) Bideau.....	656
burns; First aid treatment of —.....	1171
from calcium nitrate; Manufacture of —. (P) Chem. Werke vorm. Byk.....	365
Concentration of —. (P) Swedish Nitric Syndicate.....	1197
Concentration of dilute —. (P) Uebel.....	794
Determination of — gravimetrically. Hes.....	162
Determination of — by means of nitron: Paal and Gaugheider.....	918
Poeth.....	677
Determination of — by nitron in liquids containing much organic matter. Franzen and Löhmann.....	546
Extraction of — from mixtures containing sulphuric acid. (P) Swedish Nitric Syndicate.....	1197
Influence of small quantities of elements in copper on its reactions with —. Stansbie.....	268
Manufacture of —: (P) Chem. Werke vorm. H. Byk.....	982r, 1033
(P) Dieffenbach and Moldenhauer.....	365r
(P) Schmidt.....	937
(P) Valentiner und Schwarz.....	600r
Manufacture of — by combustion. (P) Badische Anilin und Soda Fabrik.....	599
Manufacture of commercially pure —. (P) Salpetersäure-Ind. Ges.....	473
Manufacture of concentrated — free from nitrous compounds. (P) Douzal.....	599

Nitric acid— <i>cont.</i>	
Dehydration of — (P) Oberhayerische Kokswerke	
Manufacture of — from gas mixtures containing nitro-	
gen oxides. (P) Glaszr. and General Electric Co.	656
with metals; Reactions of —. Stansbie	272
Production of — by electric discharge. Cramp and	
Hoyle	95
"vapours": Apparatus for condensing and absorbing —.	
(P) Scherfenberg and Prager	90
Nitric oxide from air; Formation of — by a low-voltage	
electric current. Morden	520
Concentration of — (P) Allgem. Elektrizitäts Ges.	937
Manufacture of — (P) Dietsenbach and Moldenhauer	365r
Nitriles; Preparation of <i>o</i> -nitro-compounds of aromatic	
(P) Kalle und Co.	815
Nitrimethylene sulphonylates. (P) Chem. Fabr. von Heyden	1326
Nitrite solutions; Purification of — (P) Norsk Hydro-	
Elektrisk Kvalstofaktiesselskab.	91r
Nitrites; Action of carbon dioxide on —. Marle	307
Analysis of —. Sanin	1248
Conversion of — into nitrates. (P) Badische Anilin	
und Soda Fabrik.	884
Determination of —. Zeller	856
in drinking water; Reaction for —. Roehaix.	324
Electrical production of — (P) Bunet and Badin.	1198
and nitrates; Formation of mixed crystals of alkali —.	
Bruni and Meneghini	1123
in water; Fuchsin-S as standard for determination of	
— Kastle and Elvove	742
<i>p</i> -Nitro- <i>o</i> -anisidine; Nitrosamine of — and its application:	
Bourcart	699
Dziewonski and others	699
<i>o</i> -Nitroarylnitriles; Preparation of — (P) Kalle und Co.	815
Nitrobenzene; Manufacture of — (P) Saccharin-Fabr.	
vorm. Fahlberg, List, and Co.	1118
<i>o</i> -Nitrobenzamide from <i>o</i> -nitrobenzaldehyde; Preparation of	
(P) Kalle und Co.	108
<i>p</i> -Nitrobenzoic acid <i>n</i> -propyl ester. (P) Fritzsche und Co.	814
<i>o</i> -Nitrobenzonitrile; Preparation of — from <i>o</i> -nitrobenzal-	
dehyde. (P) Kalle und Co.	108
<i>p</i> -Nitrobenzyl alcohol; Preparation of — (P) Dietsenbach	1326
Nitrocellulose from agaves. Carniero	384
Dehydration of — (P) Gentien	1065
powders; Manufacture of gelatinous — (P) Cyanid-	
Ges.	162
Preparing wood pulp for making — (P) Opfermann	
and others	1270
Recovery of solvents of — (P) Fabr. de Soie Artif.	
de Tubize	1084
Solvent for — (P) Sauversac	1310
Nitrocelluloses; Ignition points of —. Finzi	676
6-Nitro-3-chloro-1-aminobenzene and its -4-sulphonic acid;	
Preparation of — (P) Badische Anilin und Soda	
Fabrik	304
Nitro-compounds; increasing the density of fusible explosive	
(P) Bichel and others	817r
Manufacture of — (P) Boeters and Wolfstein	695r
Preparation of aromatic — (P) Chem. Fabr. Grünau,	
Landshoff, and Meyer	360
Preparation of aromatic hydroxylated — (P)	
Wolfenstein and Boeters	1167
Reduction of aromatic — by sodium disulphide.	
Blanksma	469
<i>o</i> -Nitro- <i>p</i> -cresol; Behaviour of — towards sulphuric acid.	
Schultz and Löw	303
Manufacture of — (P) Meister, Lucius, und Brüning	328
Nitro-derivatives of benzene; Home Office Regulations for	
manufacturing —	134
Nitrogen from air; Production of —:	
(P) Blagburn	794
(P) Hurford	243, 365r, 709r, 1088r
Assimilation of atmospheric — by micro-organisms	
occurring in soil. Stránák	804
in coal gas and other gases; Determination of —.	
Von Knorre	786
from combustion gases; Preparation of pure — (P)	
Frank and Caro	90, 939r
Determination of nitrate- and nitrite- —. Zeller	856
Determination of — in potassium nitrate. Kleiber	521
Determination of total — by the Kober method. Gill	
and Grindley	1276
Fixation of — by alcohol by silent discharges. Löb	1005
in gelatinised powder; Determination of —. Poppen-	
berg and Stephan	1064
hydrogen, and metals; New compounds of —. Dufort	
and Miklausz	1125
in organic substances; Determination of —. Bennett	291
Oxidation of atmospheric — electrically. (P) Helbig	800r
Separation of — from oxygen. (P) Pictet	522r
Utilisation of atmospheric —. Berntsen	706
Nitrogen compounds; Electrolytic production of — (P)	
Acker	371
compounds of the fundamental rocks. Hall and Miller	432
hydrophosphide; Preparation of — for carburetted	
alcohol for motors. (P) Barbier	592
oxides; Apparatus for moving and conveying hot —.	
(P) Ostwald	365
oxides; Formation of — in ozonising air. Bonjean	100

Oils, Fatty—<i>cont.</i>		Ores—<i>cont.</i>	
Use of miscibility curves in analysis of edible —		Calcining, desulphurising, agglomerating, and sintering	
Louise	892	— (P) Weeks, and Ohio and Colorado Smelting	
Value of the Polenske test in analysis of —. Tatlock		and Refining Co. 479, 1206r	
and Thomson	69	Chloridising — (P) Diehl	1256
Vegetable oils; Improving the odour of — (P)		containing sulphur; Treating — before smelting. (P)	
Filbert	999	Savelsberg	942
Whale oil industry of Natal	944	Cyanide process for extracting precious metals from —	
Oils, Hydrocarbon:		(P) Just Mining and Extraction Co. 247r	
Converting — into light oil or petrol. (P) Noad and		Desulphurising — (P) Hübner	95
Townsend	84, 133r	Desulphurising and agglomerating — (P) Robinson	840
Desulphurising — (P) Robinson, and Standard Oil		Electric furnace reduction of — Richards	716
Co. 198		Electric furnaces for treating —:	
Gas oils: Valuation of —. Kallbuss	1186	(P) Aktiebolaget Elektrometall	1047
Light oils from natural gas; Recovery of —. Gray		(P) Oesterle	944
Lubricating oils; New values in the analysis of mineral		Extraction apparatus for — (P) Chamberlain	145
— Kissling	84, 594	Extraction of metals from —:	
Mineral oil; Examination of — for fatty oil. Schwarz		(P) Collins and Stevens	528
and Marcusson	468	(P) Junquera	370, 943r
Mineral oil industry of Batoum	515	(P) Smith	840
Mineral oil; Reducing the freezing point of — (P)		(P) Stevens	1142
Whitney, and General Electric Co. 594		(P) Williams	799, 799r
Mineral oil; Refining — by the dry process. Schulz		Furnaces for reducing —:	
Mineral oils; Decomposition and treatment of —		(P) Gröndal, and Amer. Gröndal-Kjellin Co. . . 1141	
(P) Tanne and Oberländer	84	(P) Rendall, and American Reduction Co. . . 207, 1205	
Mineral oils; Determination of asphaltum in dark —		Furnaces for roasting —:	
Holde	831	(P) Daniel and Römer	527
Mineral oils in Greece; Customs duties on	1319	(P) Mount and Pfleger	27r
Mineral oils in Spain; Tariff classification of —		Furnaces for smelting — (P) Kemp and others ..	1141
Mineral oils; Treatment of — (P) Hood and Salomon		Furnaces for treating — (P) Fennell and Sackett	1204
Oil mixtures; Comparison of calculated and determined		Oxidation of — (P) Eldred, and Combustion Utilities	
viscosity; numbers, flashing and burning points of		Co. 1043	
Sherman and others	17	Oxidation and cyanidation of —. Megraw	1136
Petroleum spirit; Commercial — Rakusin	17	of precious metals; Treatment of —:	
Recovery of — from waste acid. (P) Stolzenwald		(P) Clancy Metals Process Co. 1044	
1081, 1119		(P) Mosher, and Ammonia Cyanide Eng. Co. . . 247	
Tar oils; Purification of — (P) Feld	419	Preventing concretion of — in mechanical roasting	
Treatment of — to produce volatile spirit. (P) Noad		furnaces. (P) Kaulmann	480
and Townsend	133r	Recovery of metalliferous fumes in roasting or smelting	
<i>See also Paraffin and Petroleum.</i>		— (P) Schillot and Maclaure	1143r
Ointment; Non-odorous phenolic — (P) Sulzberger ..	1273	Reduction of —:	
Ojak fruit; Oil of —. Krause and Diesselhorst	892	(P) Becket	990
Oleic acid; Action of ozone on —. Harries	250	(P) Becket, and Electro Metallurgical Co. 800	
with palmitic and stearic acids; Solidifying points of		(P) Dawson, and American Reduction and Re-	
mixtures of —. Carlinfanti and Levi-Malfano ..	1318	fining Co. 1142	
Oleine-vaseline for lubrication from seaweeds. (P) De la	1211	(P) Hiorth	1091r
Guérrière	842	(P) Rendall, and American Reduction Co. 1043	
Oleoresin of <i>Copaifera paupera</i>. Hartwich and Jama ..	1062	(P) Wikström	370r
of vanilla. (P) Sheehan, and San Gabriel Valley Fruit		Reduction of complex sulphide or other — (P) Angel	798
Products Co. 932		Reduction of — electrically. (P) Tone	661
Olive kernels; Agglomerating charcoal obtained by distilling	932	Removal of sulphur, arsenic, &c., from refractory —	
— (P) Las Industrias del Olivo	932	(P) Cotton	660
kernels; Continuous distillation of — (P) Las		Roasting and sintering — (P) Dwight and Bennett	427

Reducing and melting —. (P) Frick	1047		
Reduction of —. (P) General Electric Co.	982		
Reduction of metallic —. (P) Chatillon	479		
Reduction of refractory —. (P) Kühne and Titan-Ges.	207r		
Oxidising agent: Manufacture of an —. (P) Soc. Electrolytique des Acétates Français	932		
agents: Electrolytic manufacture of — without a diaphragm. (P) Siemens and Halske A.G.	249r		
agents: Electrolytic production of —. (P) Thiele	96		
Oxyarylarsonic acids: Reduction products of —. (P) Meister, Lucius, and Brining	328, 543r		
Oxydases. Dony-Hénauld	919		
Artificial —. Martinand	222		
of <i>Rosaula delicata</i> : Properties of the —. Wolf	445		
Use of hydrogen peroxide in experiments on —. Kikkeli and Neuberg	1068		
Oxygen from air: Apparatus for separating —. (P) Johansen	1035		
Detection of —. Winther	746		
Electrolyzers for producing pure —. (P) Eycken and others	799		
Extraction of atmospheric —. (P) Desours-Desaetes and hydrogen generators: Electrical —. (P) Cowper-Coles	657, 95		
Manufacture of —: (P) Ridley	881		
(P) Winand	1127		
Manufacture of compounds containing active —. (P) Merck	1087		
Manufacture of — by electrolysis of water. (P) Varelle	522		
		P	
		Packing: Manufacture of —. (P) Murphy	929
		pieces for absorption, condensing, and like towers. (P) Peyton	828
		Paint: Antifouling —. (P) Bayer and Co.	98, 98r
		for use as antifouling composition for ships. (P) Palk and others	1319
		with base of pinaric acids derivatives: Manufacture of —. (P) Darrasse frères, and Dupont	31
		Composition for removing —. (P) Manns	895
		Manufacture of fireproof —. (P) Terrie and Cognier	1050
		Metallic —. (P) Gall	895
		removers. (P) Wilson and Harris	663
		tests. U.S. Geological Survey	1147
		vehicles: Manufacture of —. (P) Walker and Sohn	1260
		Waterproofing — for Portland cement buildings. (P) Edion, and New Jersey Paint Co.	151
		Painting: Oil substitute for use in —. (P) Silvestrini	1050
		Paintings: Formation of cracks in oil —. Täuber	209
		Paints containing lead: Importation of — into Austria-Hungary	894
		Manufacture and application of oil —. (P) Liebreich	98
		Manufacture of oil —. (P) Jagenburg	992
		Production of mineral — in the United States	1095
		Palest Islands: Phosphates in the —	883
		Palladium: Catalytic reduction with colloidal —. Paal and Gerim	624
		Palm starch for paper making. Virneisel	439
		trees: Manufacture of sheets from cores of —. (P) Von Alpenburg	541
		Palmitic acid with oleic and stearic acids: Solidifying points of mixtures of —. Carlinfanti and Levi-Maffano	1318
		Panary fermentation: Neumann and Mehs	1099
		Vandevelde	809
		Pancreas: Hydrolysis of fats by —. Baur	149
		preparation for treating diabetes. (P) Chem. Fabr. vorm. Schering	442
		Papaverine: Synthesis of —. Pictet and Gams	905
		Paper. (P) Diekln	439
		Action of — on metals. Klemm	742
		Agent for sizing —. (P) Curtius and Co.	380, 623r
		Apparatus for treating fibres in making —. (P) Sparte	958
		in Canada: Manufacture of —	743
		Chromates as coloring matter for —. Skark	850
		Converting old — into pulp for re-manufacture. (P) Herz	811, 1271r

Sizing composition. (P) Rossi	1195	Dominkiewicz	801
ingredient for textiles. (P) Richardson	1122	Fendler and Frank	250
paper; Agent for — (P) Curtiss and Co.	380, 623r	emulsions for washing wool, &c. (P) Crefelder Seifen- fabr. Stockhausen and Traiser	012
textiles; Process of — (P) Boyeux	1085r	frames. (P) Jacobi	802
Skins; Degreasing — (P) Derooy	211	Hydrolysis of — Ross	30
Machine for applying liquid to — (P) Turner, and Turner Tanning Machine Co.	485r	Manufacture of —	
Machine for earrotting — (P) Beaulieu	882	(P) Ellis, and Ellis-Foster Co.	30
Machine for treating — (P) Slocumb	1263	(P) Grant	1319, 1319r
Removing grease and lime from and disinfecting — (P) Lehmann	1151, 1213r	(P) Jackels	1147
Tanning —		(P) Rivière	317, 992
(P) Nance	101, 432r	(P) Schou	482r
(P) Schmid, and Boehringer Sohn	1212	Manufacture of albumose — (P) Runge	373
Tanning and treating — (P) Robeson	1052, 1052	Manufacture of — in granular, flaked, or like con- dition. (P) Reif	802, 842r
Treatment of — (P) Vidal	1262	Manufacture of hygienic — (P) Radisson	894
Treatment of tanned — (P) Spigio	721	Manufacture of — or mixtures containing soap. (P) Samuel and others	532r
Tumblers for tanning and treating — (P) Bedford and others	484	Manufacture of powdered — (P) Gebr. Körting	992, 1319r
Slag; Basic; Amount of free lime and composition of soluble phosphates in — Morison	1214	press with cooling device. (P) Klumpp	894
cement; Manufacture of — (P) Rhodin	984	Rosin; Manufacture of — (P) Carnichael	151
Generation of steam from the heat contained in — (P) Vautin	987	or soap compound. (P) Hollingworth	992
Granulation of — (P) Pyrotrass Soc. Anon.	1091r	solutions; Action of carbon dioxide on — Fendler and Kulm	151
Granulators for molten — (P) Warren	1037	stock; Determination of fatty acids in —	1210
Lime in basic — Hendrick	775	Soaps; Colloidal solutions of calcium — in heavy mineral oils. Holde	98
Manufacture of building stones, &c., from — (P) Cöln-Müsener Bergwerks Akt.-Ver.	244	containing int. solvents; Manufacture of — (P) Welter	1211, 1319r
Manufacture of cement from blast-furnace — (P) Metzger	1251	containing mercury compounds; Manufacture of — (P) Bayer and Co.	1211
Manufacture of hydraulic cement from blast-furnace — (P) Grau	24	containing peroxides; Manufacture of — (P) Beiers dorf and Co.	30r, 532r
for road building; Composition and properties of — Lord	711	Detergent action of — Spring	430
		Manufacture of — (P) Irving	482
		Manufacture of soda and potash — from ammonia soaps. (P) Barbé and others	603r
		Manufacture of solutions of resinous — (P) Arledter	317
		Process and apparatus for making — (P) Rivière	317
		Toilet cleaning — (P) Lyon	1048
		In Turkey	944
		Valuation of solutions of cresol —	
		Schmatolla	380
		Spalteholz	256

	PAGE
Soaps— <i>cont.</i>	
Working up acid waters obtained in decomposing — of metals. (P) Kellner	612
Sobrerol; Conversion of pinene into —. Henderson and Eastburn	1102
Soda-ash; Causticising recovered —. Schacht	324
lye. See Sodium hydroxide lye.	
Sodium; Electrolytic manufacture of —. (P) Soc. d'Electro-Chimie, and Hulin	149, 1145r
-potassium alloys; Formation of —. Jaubert	25
Sodium acetate; Electrochemical manufacture of —. (P) Jacob	21, 208r
alum. Smith	242
alum free from iron; Preparation of —. (P) Kaufmann	1314
aluminate lyes; Manufacture of —. (P) Vergé	708
aluminate; Rendering silica in — insoluble. (P) Peniakoff	939r
-amino compounds from primary or secondary aromatic amines. (P) Basler Chem. Fabr.	161
p-aminophenylarsinate; Distinguishing — from sodium p-acetaminophenylarsinate. Labat	160
p-aminophenylarsionate. Martindale	910
arylimides; Preparation of —. (P) Deuts. Gold- u. Silber-Scheide-Anstalt	1223
benzoate as preservative for foodstuffs. Report of U.S. Referee Board	215
benzoate as preservative for foodstuffs; Use of —. U.S. Food Inspection Decision	670
bicarbonate; Dissociation of —. Soury	20
bicarbonate; Manufacture of —. (P) Peniakoff 1034, 1314r	
bisulphate; Utilising — for making hydrochloric acid and sodium sulphate and carbonate. (P) Courtois	707
carbonate; Crystallisation of — on sawdust. (P) Dieres-Monplaisir	600
carbonate; Manufacture of hydrated —. (P) Ride-nour	309
carbonate solutions; Spontaneous crystallisation of —. Jones	1195
-carbonate. Habermann and Kurtenacker	833
chloride; Boiling point of —. Emich	1085
compound of indene. (P) Ges. f. Teerverwerthung.	84, 649
cyanide; Manufacture of —. (P) Tcherniac	794
glycerylphosphate; Preparation of —. (P) Wülling	161
hydrosulphides, sulphide, and polysulphides. Bloxam	138
hydrosulphite; French denaturation tax on alcohol for use in making —	1085
hydrosulphite and zinc dust; Decolourising product composed of —. (P) Badische Anilin und Soda Fabrik	1087
hydroxide; Electrolytic preparation of — from the chloride. (P) Lévy	1125
hydroxide lye; Removing — from fabrics after mercerising. (P) Venter	19
hydroxide; Manufacture of — from recent eruptive stones. (P) Schäcke	365r
hypochlorite; Electrolytic preparation of —. Oglobin iodide and dextrose; Crystalline double compound of —. (P) Wülling	1085
metasilicate; Binary systems of — with other metasilicates. Wallace	793
methylarsionate. Martindale	907
nitrate from caliche; Lixiviating apparatus for extracting —. (P) Love	708
nitrate combine; Expiration of the —	599
nitrate; Consumption of — in the United States. Munroe	598
nitrate; Manurial value of — for the sugar beet. Urban	666
nitrate statistics. Montgomery and Co.	21, 706
nitrite; Manufacture of —. (P) Dittrich	1035
nitrite and nitrate; Formation of mixed crystals of —. Bruni and Meneghini	1123
nitrite and potassium nitrate; Simultaneous manufacture of —. (P) Soc. Le Nitrogène	1087
oxides; Electrolytic manufacture of —. (P) Carrier	248
perborate; Manufacture of —. (P) Von Girsowald	90
perchloride, perbenzoate, and performate. (P) Jaubert	938
peroxide composition for washing and bleaching. (P) Gruen	663, 833r
peroxide in organic analysis; Use of —. Pringsheim	44
peroxide; Treatment of —. (P) Parker	1126
persulphate; Electrolytic preparation of —. (P) Verein. Chem. Werke.	96, 96
silicate; Increasing the mobility and reactivity of —. (P) Eberhard	794r, 835r
silicate solution; Influence of calcium carbonate on —. Kallauer	1248
sulphate deposit in California	655
sulphate; Manufacture of —: (P) Peniakoff	937
(P) Pennock, and Sulvay Process Co.	656
(P) Zahn	600r
sulphate; Manufacture of — from ashes of brown coals. (P) Chem. Fabr. Buckau	656
sulphate; Manufacture of — together with phosphoric acid. (P) Strickler	473
sulphide; Manufacture of —. (P) Strickler, and General Electric Co.	794
sulphide; Manufacture of infusible —. (P) Hasenbach	365r
sulphide and ammonium chloride; Manufacture of —. (P) Friedrich und Co.	1034, 1249r

	PAGE
Sodium— <i>cont.</i>	
sulphite; Detection of — in presence of sulphate and thiosulphate. Weston	1123
sulphite and its equilibrium with water. Hartley and Barrett	792
thiosulphate solutions; Spontaneous crystallisation of —. Jones	1195
Soil acidity in relation to lack of available phosphates. Stoddart	320
Decomposition of nitroline in the —: Kappen	153
Löbhois and Moll	153
Effect of partial sterilisation of — on production of plant food. Russell and Hutchinson	1213
tatigue caused by organic compounds. Schreiner and Sullivan	485
nitrogen of Nebraska prairies. Relation of native leguminous plants to —. Alway and Pinckney	1263
potash. Fraps	721
samples; Preparation of — for analysis. MacNider	845
solutions; Colorimetric determination of nitrates in —. Syme	375
Soils; Acidity of —. Albert	432
Action of heat and antiseptics on —. Pickering	212
Bacteriological-chemical investigations on —. Lemmermann and others	485
Changes produced in — by steam under pressure. Lyon and Bizzell	721
Colloid chemistry in relation to —. Alexander	282
Determination of calcium carbonate in —. Marr	1213
Nitrification in —. Pouget and Guiraud	432
Nitrification and denitrification in —. Von Bazarowski	153
Rapid determination of total potassium in —. Shedd	615
Solder for aluminium. (P) Goppmann	1256
for aluminium and its alloys. (P) Mrazsek	207r
for aluminium and other metals. (P) Carroll and Adams	26
Cadmium in soft —. Sperry	659
Determination of lead in —. Della Croce	839
for incandescence lamp filaments. (P) Kuzel	237r
for platinum. (P) De Benedetti	1090
for provision tins sent to Japan; Percentage of lead in — used for tinned goods; Limit of lead in — for importation into Uruguay	379
Soldering aluminium: (P) Nielsen	1205
(P) Stadler and others	890
Autogenous —. (P) Knappich	609
Chemistry of preparations for use in —. Lippmann	1139
flux for —. (P) Ackermann	1034, 1317r
fluxes; Chemistry of —. Samter	526
Hard —. Diegel	478
metals. (P) Cie. Franç. de l'Acétylène Dissous	890
pure aluminium and its alloys. (P) De Andrade	609
Solders; Surface appearance of —. Bannister and Tabor	1139
Solid bodies from liquids; Apparatus for separating — by cooling. (P) Porges and Neumann	357r
materials; Apparatus for removing liquid from —. (P) Cockburn	299
matter; Separating — from liquids. (P) Arlücke and Osborne	356, 357r
matter; Separating — suspended — from a liquid. (P) Elmore and Elmore	194, 511r
particles; Separating — from a fluid or from each other. (P) Wärd and Wärd	15r
Solids; Apparatus for separating — from liquids. (P) Willey Mining Machinery Co. and Roubesh	1185
Centrifugal machine for separating — from liquids: (P) Aktiebolaget Separator	77, 646r
(P) Bradley	590
of different densities; Machine for separating —. (P) Baxter	1306
Separation of crushed — from liquids. (P) Arlücke and Osborne	1043
Separation of — from liquids. (P) Durant and others	691r
Solubility; Apparatus for determining —. Stolzenberg	1328
Determination of — by the Pulfrich refractometer. Osaka	625
effect of ether, phenol, chloroform, &c.; Mutual —. Fühner	441
Solution processes; Apparatus for use in —. (P) Hommel, and Metals Extraction Corporation	416, 511r
Solutions; Drying aqueous —. (P) Lehmann	897
Hardness of solid —. Kurnakow and Shemstshusly	93
Purifying — by settling. (P) Tremann	537, 617r
Separating solid impurities from viscous or gummy —. (P) Calico Printers' Assoc. and others	1023
Treatment of unstable —. (P) Alexander and others	139
Viscosity of —, and its bearing on the nature of solution. Donstan	751
Solute theory; Present status of the —. Jones	164
Solvent for fat extraction. (P) Gütan and Simonin	991
Solvents; Chlorine derivatives of ethane and ethylene as —. Koller	719
for fats and essential oils; Manufacture of —. (P) Laroche et Juillard	1147
containing glycerol; Conductivity and viscosity of mixed —. Schmidt and Jones	850

Strontium bromide; Volatility of — Stock and Heynemann	1248
dibromobehenate. (P) Bayer and Co.	626
nitrate; Manufacture of — (P) Traime and Hellmers	140
sulfide; Manufacture of — (P) Goldschmidt	97
Strychnine alkaloids; Preparation of sulphonic acids of — Leuchs and Schneider	106
Bromination of — Buraczewski and Dziurzynski	1102
Iodine derivatives of — Buraczewski and Kozniowski	38
Separation of — from brucine. Pinchbeck	905
Strychnine sulphonic acids; Preparation of isomerie — Leuchs and Schneider	905
Sublimation at low temperatures in a vacuum. Hansen	219
Subliming sulphur, &c.; Apparatus for continuously — (P) Bert	1087
Succinic acid in alcoholic fermentation; Formation of — Ehrlich	848
Sucrose in bagasse; Determination of — Prinsen-Geerlaga and hydrated maltose; Optical determination of mixtures of — Pieraerts	375
Inversion of — by ferments. Taylor	375
Inversion of — by invertase. Hudson	724
in molasses; Determination of — Andersen	805
Rôle of magnesium oxide in the hydrolysis of — Tribot	433
Sensitive reaction for — Pozzi-Escot	1155
Supposed formation of formaldehyde from — La Wall	1264
Sudan gums	536
gums; Chemistry of the — Edie	536
Production of castor oil bean in the —	1318
Sugar; Adsorption of — Rona and Michaelis	535
Adsorption of — by animal charcoal. Herzog	667
analysis; Basic lead nitrate as clarifying agent in — Herles	1055
analysis; Unification of clarification methods in — Sachs	1055
Apparatus for boiling — (P) Baker	103, 731r
Apparatus for drying — (P) Kent	950
Apparatus for making — (P) Raffinerie Moderne	33
Application of temperature corrections to polarisation of raw — with the quartz-wedge saccharimeter. Browne	616
in bagasse; Determination of — Pellet	253
beet; Comparative manurial values of calcium nitrate and cyanamide and sodium nitrate for — Urban	666
beet; Composition of the — Sallard	725
in beetroots; Determination of — Herzfeld	846
in beetroots; Determination of crystallisable — Pellet	726
from beetroots; Lixivating — (P) Egyptiennes Kizirletző Intezet	1098
beets; Extraction of — (P) Gollmert	152
beets; Optically active non-sugars of — Strohmmer and Fallada	726
beets; Sodium chloride as fertiliser for — Briem	949
Mette	805
Strohmmer and others	948
from "blackboy"; Production of — (P) Wallace and Reynaud	255
Cane — See under Sucrose.	
cane experiments in the Leeward Islands	806

Sugar—cont.	PAGE
cane; Extraction of juice from —, (P) Steffen	806
cane plantations; Manufacture of fertiliser from waste of —, (P) Van der Kolk	1216
cane; Relation between added water on — and dilution of normal juice, Pellet	486
cane seedlings in Java, Kolos	725
cane soils; Action of soluble fertilisers on —, Eckart	948
cane; Treatment of —:	
(P) Burton	257
(P) Wynberg and Wynberg	1322
cane; Wax of the —, Wijnberg	991
content of fine wheat flour, dough, and fermented dough, Von Liebig	488
Decomposition of — by alcoholic fermentation, Buchner	1098
Decomposition of — during the respiration process, Jensen	494
Determination of ash in —, Mann	728
Determination of — in cosettes, Le Docte	1154
Determination of — in saturation mud, Herles	103
diffusion juices of high density; Treatment of —, (P) Lambert	213
Diffusion juice; Purity of juices of last diffusers compared with —, Pellet	727
diffusion process and apparatus, (P) Grière	33
diffusion process; The Hyros-Rak —, Andriik and others	949
diffusion process in which the effect of the inactive space in the battery is obviated, Pácnicka	433
diffusion process; Scalding —, Kaiser	212
diffusion; Saturation devices for automatic —, (P) Vallery	898
Diffusion waste waters; Return of the —, Pfeiffer	666
estates in Java; Factory statistics of some —, Prinsen-Geerlings	846
factories; Losses in cane —, Pellet	726
factory and refinery products; Determination of dry substance in —, Pellet	728
-house; Charging diffusers used in the —, (P) Lambert	617, 898
-house products; Influence of concentration on determination of degrees Brix of impure —, Pellet and Fribourg	728
-house products; Influence of non-sugars on determination of dry substance in —, Stanek	1155
industry of Cuba, Brooks	725
industry of the Hawaiian Is.; Cane —, Deerr	725
industry of Java	845
industry of Peru; Cane —, Zerbán	725
industry of the United States, Bryan	725
Influence of opt.-active non-sugar on polarimetric determination of —, Kopecky	1215
Influence of temperature on polarisation of raw cane invert, Wiley and Bryan	1154
invert; Influence of clarification on valuation of products containing —, Prinsen-Geerlings	729
juice; Apparatus for evaporating —, (P) Greiner	807
juice boilers, (P) Degroise	1156
juice; Boiling thick — in cane sugar factories, Prinsen-Geerlings and Weitkamp	375
juice; Continuous refining and evaporating apparatus for —, (P) Tiemann	321
juice; Evaporation of — for making crystallised sugar, (P) Lagrange and Kestner	212
juice; Quantities of non-sugar precipitated from — by defecation and saturation, Claassen	616
juice; Relation between added water on cane and dilution on normal cane —, Coombes	102
juices; Action of lime on crude —, Pellet	1264
juices; Apparatus for concentrating —, (P) Radnerle Moderne	34
juices; Apparatus for controlling the boiling of —, (P) Langen	807
juices; Apparatus for filtering —, (P) Hoppe	299
juices; Continuous depositing vessel for —, (P) Tiemann	537
juices; Conversion of sulphurous acid into sulphuric acid in —, Safford and Wehrung	1215
juices; Purification of —, (P) Rivière	899
juices; Purification of — by hydrosulphuric acid, (P) Soc. Civ. des Brevets Schoonjans	1157
juices and syrups; Purification of — by calcium and aluminium silicates, Smahel	433
Making — synthetically, (P) Stewart, and National Sugar Co.	1157r
Manufacture of —:	
(P) Altodaguirre and Zubillaga	321
(P) Gailhat	153
(P) McMullen	376, 537r
(P) Von Grabski	1156
Maple; Suggested standards for —, Cowles	1264
massecuites with regular crystals; Process for obtaining crude —, (P) Tiemann	486
Milk —, See under Lactose.	
Product producing — and its conversion into sugar, (P) McMullen	103r
production in 1907-8	1156
products; Influence of clarification with basic lead acetate on valuation of —, Eynon	729
as raw material for the confectionery and preserves industries, Bosley	730
Reversion of the synthesis of —, Löb	1068

Sugar—cont.	PAGE
samples; Drying of raw — and method of avoiding it, Stanek	726
saturation muds; Examination of —, Claassen	616
solutions; Apparatus for purifying — by settling, (P) Tiemann	537, 617r
solutions; Decolorisation of —, (P) Hay and Tennent	942
solutions; Influence of surface tension of — on hydrometer readings, Delachanal	728
solutions; Preventing frothing of — during manipulation, (P) Hamelle	950
syrups; Direct conversion of — into edible sugars, (P) Grière	1216
syrups; Refractometric examination of impure —, Tschetschenko	253
Working-up residues from the manufacture of cane —, (P) Wynberg	899
works; Indanthrene dyestuffs as substitutes for ultramarine in —	805
works; Relation between apparent and real purity in products of beet and cane —, Pellet	727
works; Thin filter-press plates for —, (P) Degremont and Devaux	873
Sugars; Action of the Bulgarian ferment on various —, Bertrand and Bucháček	668
Apparatus for converting wood into fermentable —, (P) Cie. Ind. des Alcools de l'Ardeche	998r
Bacterial flora of Hawaiian —, Lewton-Brain and Deerr	845
with benzidine; Compounds of —, Adler	667
Colour reactions of —, Ville and Berrien	1055
Colour reactions of iodide substances with —, Gnezda	320
containing invert sugar; Influence of clarification on valuation of raw —, Prinsen-Geerlings	729
Decomposition of the —:	
Löb	535, 1068, 1264
Löb and Pulvermacher	617
Fixation of carbon dioxide by —, Siegfried and Howwjan	543
Method for determining the constitution of the —, Hanriot	387
reducing; Determination of —, Duschsky	847
reducing; Precipitation of — with basic lead acetate, Bryan	32
reducing; Reagent for detecting —, Benedict	385
Relation of pyridine to the —, Neuberger	1056
Sensitive reaction for —, Pozzi-Escot	1155
Spontaneous oxidation of the —, Mathews	486
o-Sulphaminobenzoic acid; Manufacture of —, (P) List, and Saccharinfabr. vorm. Fahlberg, List, and Co.	814
Sulphates; Detection of — in presence of sulphites and thiosulphates, Alexandrow	138
Determination of sulphuric acid in —, Oddo and Beretta	918
Electrolysis of alkali —, (P) Marie	1092
Extraction of metals from ores, Ac., as —, (P) Troeller and fluorides; Separation of —, Ehrenfeld and Indra	444
Formation of certain double —, Barre	882
Manufacture of metal —, (P) Meuser	600r
Manufacture of sulphur trioxide and anhydrous bases from —, (P) Prud'homme	1033
Sulphide in alkali cyanide; Determination of —, Ewan	10
ores or products; Treatment of —, (P) Hommel, and Metals Extraction Corporation	479
Sulphide dyestuffs from carbazol derivatives:	
(P) Haas	517
(P) Haas, and Cassella Color Co.	517r
Dyeing with —:	
(P) Farbwerk Mühlheim	1085
(P) Meister, Lucius, and Brüning	89r
Dyeing cotton with —, (P) Dupetit	935
Dyeing half-silk with —, (P) Farbwerk Mühlheim vorm. Leonhardt und Co.	792
Manufacture of —:	
(P) Act.-Ges. f. Anilinfabr. 19r, 305, 651r, 1082	
(P) Bayer and Co. 86r, 1190	
(P) Bundman, and Point Loma Chemical Co. 198, 198

Woods; Destructive distillation of pine, fir, beech, and birch ——— Klason and others	132
Irritant ——— Auld	624
Woody residues; Continuous distillation of ——— (P) Las Industrias del Olivo	932
substances; Saccharification of ——— and recovering by-products. (P) Bouchaud-Praceiq	103
Wool; Absorption of moisture from the atmosphere by ——— Wright	1020
Apparatus for removing grease from, and bleaching ——— (P) Bouchat	880
Apparatus for supplying liquid to ——— (P) Murray	881
A Canadian natural resource. Murray	1085r
Carbonisation of ——— (P) Floquet	1231r
Chlorinised ——— Pearson	1311
Chroming of ——— Gavard	305
Cleansing ——— (P) Shuman and Shuman	19
and cotton goods; Producing effects on mixed ——— (P) Jones, and Bayer and Co.	241r
Determination of ——— in unions. Ruszkowski and Schmidt	241r
Development of Acid Magenta printed on sulphur-bleached ——— in sunlight. Paterson	1030
dyeing machine. (P) Maly	422
Dyeing variegated shades on ——— (P) Roussel	1085, 1122r
Emulsions for washing ——— (P) Crefelder Seifenfabrik	1031
Extraction of fatty substances from moist raw ——— (P) Frank	612, 702r
fibre; Adsorption and agglutination of the ——— Justin-Mueller	430r
fibre; Effect of various mordants and dyestuffs on ——— Kertesz	306
Fixation of Scheurer mordants on ——— Möhlau	596
flock; Disinfection of ——— (P) Waess	1083
Freeing raw ——— from its yolk and grease. (P) Baudot	1000
gelatin. See under Gelatin	363r
Influence of preparing and bleaching agents on dyed ——— Valette	700
Modifying the shrinking properties of fibres or fabrics of ——— (P) Schnecker	519
Mordanting ——— with iron salts. Möhlau	1083
Properties of ——— and hydrolytic changes during dyeing. Suida	1192
Scouring ——— by electricity: (P) Baudot	470
(P) Lagye and Vandatte	934, 1122r
-scouring liquors; Apparatus for burning the evil-smelling distillation gases produced in working up ——— (P) Zahn	362
waste saturated with boiled oil; Spontaneous combustion of ——— Nowicki	317
Wort; Production of brewers' ——— (P) Breker	436r
Worts; After-saccharification of dextrinous ——— (P) Dietsche	255
Apparatus for distilling fermented ——— (P) Vallat	1267r
Determination of the colour of turbid ——— Roeder	487

X

Xanthine derivatives; Preparation of 8-substituted ——— (P) Bayer und Co.	1167
Xanthopurpurin; Manufacture of ——— (P) Meister, Lucius, and Brining	975
Xeroform; Determination of bismuth in ——— Schlenk	1273
Xylose; Determination of ——— Berzog and Hörth	667

Y

Yarns; Apparatus for drying ——— (P) Turlur	936r
Colouring ——— for making carpets, &c. (P) Bright and Eros., and Oldroyd	1311
Drying and cooling warp ——— (P) Charlesworth	423
Machinery for dyeing, bleaching, or washing ——— (P) Brintons, Ltd., and Osborn	652
Machine for dyeing, mordanting, &c. ——— (P) Kershaw and Cole	979
Producing goffering effects on ——— (P) Tredup	520
Treatment of ——— (P) Vidal	432r
Treatment of ——— by the Agostini processes. Prud'homme	652
Yeast; Action of oxygen on quiescent ——— Delbrück and Hayduck	1322
Adulteration of bakers' ——— Kopper	214
after fermentation; Life of ——— Kayser and Hemolon	900
Beetroot syrup for the cultivation of ——— (P) Kruis	1322
Behaviour of wheaten flour towards bakers' and brewers' ——— Baker and Hulton	778
Carbon dioxide value of pure compressed ——— alone and mixed with starch. Bryan	378
cell juice; Action of colloidal ferric hydroxide on ——— Resenschek	34
cells Staining methods for determining dead ——— Schlichting and Winther	807

Yeast—cont.

contaminated with lactic acid bacteria; Influence of pasteurising temperatures on top-fermentation beer ——— Schönfeld and Rommel	951
Desiccation of ——— (P) Humphrey	377
Distribution of phosphoric acid in ——— Heinzelmann	1322
Invertase of ——— Salkowski	951
juice; Action of antiseptics on enzymes of pressed ——— Ducháček	732
juice; Fermentation of dextrose, mannose, and fructose by ——— Harden and Young	1157
juice; Fractional precipitation of expressed ——— Buchner and Ducháček	154
juice; The hexose-phosphate formed by ——— from hexose and phosphate. Young	1322
juice; Role of the enzymes in ——— Buchner and Haehn	899
Manihot root as raw material for making ——— Lange	618
manufacture; Malting, malt, and lactic digestion in ——— Sorel	733
Medicinal preparation from ——— (P) Ascoli	913
Nuclein ferments of ——— Straughn and Jones	848
Poison secreted by ——— Fernbach	996
preparation suitable for hypodermic injection. (P) Ascoli	491r
Purification of infected ——— Thevenot	1157
Removal of ——— from waste liquors of breweries and distilleries. (P) Hampton	104
Saccharomyces from saké ——— Nakazawa	434
Separation of inferior from normal ——— (P) Selg and Guntrum	619
A yeast poison in ——— Hayduck	486
Ylang-ylang oil. See under Oils, essential.	
Yoghourt; Action of the ferment ——— on various sugars. Bertrand and Ducháček	668
Yohimbé bark and its recognition in preparations. Griebel	217
Ytterbia earths; Separation of thorium from ——— (P) Rosenheim and others	1223

Z

Zachun oil. See Balanites aegyptiac oil, under Oils, fatty.	
Zeolite; Artificial ——— (P) Gans and Riedel	365r
Zeolites in agriculture; Application of ——— Gans	102
Zeuthen's method of washing hide-powder. Paessler	1097
Zinc alloys. Curry	1254
Apparatus for extracting ——— (P) Shortman, and New Delaville Spelter Co.	95r
blende; Interaction of carbon and silicon with ——— at high temperatures. Fraenkel	1253
blende; Separation of ——— from other metalliferous constituents. (P) Horwood	942
-coated metals; Testing ——— Walker	1139
coatings; Electrolytic production of ——— Richter	143
condenser. (P) Johnson, and Continuous Zinc Furnace Co.	1090
Continuous extraction of ——— from its sulphide. (P) Heskett	206
-copper alloys; Electro-deposited ——— Field	891
-copper alloys; Manufacture of ——— (P) Elliott	890
-copper alloys; Volume changes in ——— Turner and Murray	1137
Determination of ——— Voigt	1253
Determination of ——— by means of ammonia. Vaubel	1008
Determination of ——— with mercury cathode and rotating anode. Kollock and Smith	546
Determination of ——— volumetrically. Baeovescu and Vlahuta	918
dust; Manufacture of ——— (P) Cowper-Coles	715r
Electric furnace for continuous extraction of ——— from ores. (P) Côte and Pierron	801r
Electrolytic winning of ——— (P) Siemens und Halske A.-G.	1093r
Extraction of ——— (P) Shortman, and New Delaville Spelter Co.	27r
Extraction of ——— from acid solutions. (P) D'Alton-Shee	26
Extraction of ——— from its ores. (P) Queneau	1318
Extraction of ——— from ores, &c., as oxide, sulphite, or sulphate. (P) Troeller	481r
Extraction of ——— from ores by the precipitation process. (P) Imbert	144, 943r
Extraction of ——— from ores and residues. (P) Hommel, and Metals Extraction Corporation	427, 1143r
Extraction of ——— from sulphide ores. (P) Vuizner	247
furnaces; Charging the retorts of ——— (P) Dor-Delattre	206, 370r
furnaces; Extraction of dust or fumes from ——— (P) Dor-Delattre	528r, 609r
Furnaces for obtaining ——— (P) Armstrong	839
Gases occluded in ——— Delachanal	368
-lead ores; Treatment of refractory ——— (P) Isherwood	799r
Manufacture of ——— (P) Loiseau	661r
ores; Apparatus for smelting ——— (P) Hopkins	370r, 714, 1045r
ores; Continuous treatment of ——— (P) Imbert Process Co.	1142

Chemistry; Laboratory guide of industrial — (Rogers).....	446	Lack- u. Firnis-fabrikation; Die — (Bottler).....	223
Chemistry; Practical — for public schools. (Ryley).....	1107	Leather; Manufacture of — (Bennett).....	1106
Chimica generale applicata all'industria. Vol. II. Chimica organica. (Molinari).....	924	Lebens; Beiträge zu einer Kolloidchemie des — (Liesegang).....	1431
Chimie; Histoire du développement de la — depuis Lavoisier jusqu'à nos jours. (Ladenburg).....	166	Malay States; Report of Resident-General of the Federated — for 1907.....	167
Coal tables, 1907.....	264	Medicinal barks; American — (Henkel).....	1069
Coal-tar and ammonia. (Lunge).....	1329	Metal corrosion and protection.....	1010
Colloids and the ultramicroscope. (Zsigmondy).....	629	Metalle; Physikalische Chemie der — (Schenck).....	263
Commissioners of Customs; 53rd report of the —.....	1069	Metalliferous waste; Systematic treatment of — (Parry).....	331
Denrées alimentaires; Methodes officielles pour l'analyse des —.....	1227	Metallografia applicata ai prodotti siderurgici. (Savoia).....	1107
Diamonds. (Crookes).....	1329	Metallographie. (Guerlier).....	1106
Dyeing and cleaning of textile fabrics; The — (Owen).....	332	Mineral resources of the United States. (1907).....	332
Dyeing in Germany and America. (Higgins).....	924	Mineralöle und Fette, sowie ihnen verwandten Stoffe; Untersuchung der — (Holde).....	1227
Dyeing and textile chemistry; Laboratory manual of — (Matthews).....	495	Mines and quarries; General report and statistics for 1907. Part IV. Colonial and Foreign.....	859
Eisens; Beiträge zur Kenntniss des elektrochemischen Verhaltens des — (Foerster).....	1171	Mines and quarries; General report and statistics for 1908. Part I. District statistics.....	859
Electrochemical centres; Some — (Pring).....	44, 924	Mines and quarries; General report and statistics for 1908. Part II. Labour.....	1069
Elektrochemie u. angew. physikalischen Chemie; Jahrbuch der —.....	859	Mines and quarries; General report and statistics for 1908. Part III. Output.....	1227
Elektrochemischen Verfahren der chemischen Gross-Industrie; Die — (Biltz).....	924	Oils, fats, and waxes; Chemical technology and analysis of — (Lewkowitsch).....	494
Elektrolytische Zähler. (Norden).....	114		
Erden; Verhalten der wichtigsten seltenen — zu Reagentien. (Von Panayeff).....	819		
Erdöl-Industrie; Laboratoriumsbuch f. die — (Kissling).....	223		

	PAGE		PAGE
Organic chemistry: Modern —. (Keane).....	446	Soya beans; Cultivation and uses of —. (Edie)	1227
Patent Office Library: List of works on laws of industrial property and copyright in the —.	924	Sprechsaal-Kalender, f. die keramischen, glas-, u. verw. Industrien	44
Patents, designs, and trade-marks; Report of Comptroller-general. (1908)	495	Statistical abstract for the British Colonies, Possessions, and Protectorates, 1893-1907	44
Paper making; Bamboo for —. (Sindall)	924	Statistical abstract for the British Empire, 1893 to 1907	224
Pharmacopoeia of the United States; Comments on the —. (Mottet and Wilbert)	923	Statistical abstract for foreign countries, 1896 to 1905-6	44
Pharmacy; Year-book of —.	166	Statistical abstract for the United Kingdom, 1894-1908	965
Philippine Islands; New Customs tariff of the —.	1172	Statistical tables relating to British Colonies, Possessions, and Protectorates, 1906	113
Physical chemistry; Exercises in —. (Roth).....	753	Stearinfabrikation; Die —. (Lach)	112
Physical chemistry; Outlines of —. (Senter)	224	Steels, steel-making alloys, and graphite; Rapid methods for the chemical analysis of special —. (Johnson)	223
Physical and inorganic chemistry; Recent advances in —. (Stewart)	1172	Sugar; Cane — and its manufacture. (Prinsen-Geerligs)	753
Pigments; Lead and zinc —. (Holley).....	1010	Sulphuric acid and alkali, &c. Vol. 2. Sodium sulphate, hydrochloric acid, and Leblanc soda (Lunge) ..	1329
Plomb et du mercure; Industries du —. (Buchonnet)	548	Thermo-chemical constants; The calculation of —. (Redgrove).....	263
Poisoning; Tables of cases of industrial —, and accidents and dangerous occurrences in factories, workshops, &c., during 1908	388	Tinktorial-Chemiker, Koloristen, Ingenieure, u. techn. Reisende in Färbereien, Druckereien, Farben-, Lack-, u. Papierfabr.; Laboratoriumsbuch f. —. (Erban)	113
Poisonous substances for agriculture and horticulture; Order in Council making regulations as to the sale of certain —.	496	Tonindustrie Kalender	113
Poisons and Pharmacy Act, 1908	167	Trade and industry: Statistical tables and charts relating to British and Foreign —. 1854-1908.	1278
Polarisation; Die elektromotorischen Kräfte der — und ihre Messung mit Hilfe des Oszillographen. (Le Blanc).....	133	Trade of the United Kingdom; Annual Statement of —. Vol. I.	820
Radio-activity; Introduction to the science of —. (Raiffety)	223	Vol. II.	965
Rarer elements; Introduction to the —. (Browning) ..	113	United Kingdom; Imports and exports of the — at prices of 1900	1069
Reval Commission on whisky and other potable spirits. Minutes of evidence, Vol. 2	1069	United States; New Customs tariff of the —.	1010
Index and digest of evidence	1069	Universität Zürich; 75 Jahre chem. Forschung an der —	548
Rubber goods; The manufacture of —. (Heiland Esch) ..	629	Valency; The theory of —. (Friend)	223
Rubber; The universal standard grading of scrap —. (Leslie)	1330	Van Nostrand's chemical annual, 1909	1277
Salzlösungen; Gesättigte — vom Standpunkt der Phasenlehre. (Jaenecke)	166	Water analysis; Laboratory notes on industrial —. (Richards)	113
Scientific literature; International catalogue of —. D. Chemistry	264	Wellsome Research Laboratories, Khartoum; Third report of the —. (Balfour)	495
		Zinco; Lo —. (Muscroy)	1107

INDEX OF NUMBERS OF ENGLISH PATENTS ABSTRACTED.

LIST OF JOURNALS ABSTRACTED, WITH ABBREVIATIONS USED, AND ADDRESSES OF PUBLISHERS.

JOURNAL.	ABBREVIATION.	ADDRESS OF PUBLISHER.
Agricultural Ledger	Agric. Ledger	Reporter on Economic Products to the Government of India, Calcutta. Michaelerstrasse 25, Vienna XVIII/1.
Allgemeine Zeitschrift für Bierbrauerei und Malzfabrikation ..	Allgem. Z. Bierbrau. u. Malzfabr. ..	The Johns Hopkins Press, Baltimore, Md., U.S.A.
American Chemical Journal ..	Amer. Chem. J. ..	Simpkin, Marshall, Hamilton, Kent, and Co., Ltd., 10, James Street, Haymarket, London, S.W.
Analyst	Analyst	C. F. Winter'sche Verlagshandlung, Leipsig, Germany.
Annalen der Chemie	Annalen	M. Crinon, 45, Rue Turenne, Paris, 3 ^e . 16, Place Vendôme, Paris.
Annales de Chimie Analytique ..	Ann. Chim. Analyt. ..	Selbstverlag des Deutschen Apotheker-Vereins, Berlin, Germany.
Annales des Falsifications ..	Ann. Falsific. ..	R. Friedländer und Sohn, Karlstrasse 11, Berlin, N.W., 6, Germany.
Archiv der Pharmazie	Arch. Pharm.	Verlag von Gebr. Bornträger, Berlin, W. 35, Schöneberger Ufer 12A, Germany.
Berichte der Deutschen Chemischen Gesellschaft	Ber.	O. Leiner, Königstrasse, 26n, Leipsig, Germany.
Berichte der Deutschen Pharmazeutischen Gesellschaft ..	Ber. deuts. Pharm. Ges. ..	Bio-chemical Dept., The University, Liverpool.
Biedermann's Zentralblatt für Agricultur Chemie	Biedermann's Zentr. ..	Verlag von J. Springer, Berlin, N. 24, Monbijouplatz 3.
Bio-chemical Journal	Bio-chem. J.	Messrs. Wyman and Sons, Fetter Lane, London, E.C.
Biochemische Zeitschrift	Biochem. Zeits.	F. W. Lyon, Eastcheap Buildings, Eastcheap, London, E.C.
Board of Trade Journal	Bd. of Trade J.	44, Bishopsgate Without, London, E.C.
Brewers' Journal	Brewers' J.	M. le Trésorier, 156, Boulevard Magenta, Paris, 10 ^e , France.
British and Colonial Druggist ..	Brit. and Col. Drug. ..	M. J. Wauters, Palais du Midi (Galerie du Travail, 7), Brussels.
Bulletin de l'Association Chimique de Sucre et de Distillerie ..	Bull. Assoc. Chim. Sucr. ..	Masson et Cie., 120, Boulevard Saint-Germain (6 ^e), Paris.
Bulletin de la Société Chimique de Belgique ..	Bull. Soc. Chim. Belg. ..	51, Rue de Clichy, Paris, 9 ^e .
Bulletin de la Société Chimique de France ..	Bull. Soc. Chim.	Rue de l'Hôpital Militaire 114 et 116, Lille, France.
Bulletin de la Société Française de Photographie ..	Bull. Soc. Franç. Phot. ..	Berger-Levrault et Cie., 5, Rue des Beaux-Arts, Paris.
Bulletin de la Société Industrielle du Nord de la France ..	Bull. Soc. Ind. Nord	Secrétariat, Rue de Rennes 44, Paris, France.
Bulletin de la Société Industrielle de Mulhouse ..	Bull. Soc. Ind. Mulhouse ..	Director of the College of Agriculture, Tokyo Imperial University, Japan.
Bulletin de la Société d'Encouragement pour l'Industrie Nationale ..	Bull. Soc. d'Encour.	A. D. Gillard fils, 49, Rue des Vinaigriers, Paris, X.
Bulletin of the College of Agriculture, Tokyo Imperial University, Japan ..	Bull. Coll. Agric. Tokyo ..	Oxford Court, Cannon Street, London, E.C.
Le Caoutchouc et le Gutta-Percha ..	Caoutchouc et Gutta-Percha ..	E. J. Davey, 16, Newcastle Street, Farringdon Street, London, E.C.
Chamber of Commerce Journal	Ch. Comm. J.	Davis Bros., Danes Inn House, 265, Strand, London, W.C.
Chemical News	Chem. News	Dr. G. Krause, Cöthen, Anhalt, Germany.
Chemical Trade Journal	Chem. Trade J.	Weidmann'sche Buchhandlung, Zimmerstrasse 94, Berlin, S.W., Germany.
Chemiker-Zeitung	Chem.-Zeit.	Dr. Maschke, Wallenstein und Co., G.m.b.H., Catherinestrasse 16, Hamburg, Germany.
Chemische Industrie	Chem. Ind.	R. Friedländer und Sohn, Karlstrasse 11, Berlin, N.W., 6, Germany.
Chemische Revue über die Fett- und Harz-Industrie	Chem. Rev. Fett-Ind. ..	42, Cannon Street, London, E.C.
Chemisches Zentralblatt	Chem. Zentr.	K. Schorlemmer, Huttenstrasse 7, Worms am Rhein, Germany.
Chemist and Druggist	Chem. and Drug.	Imprimerie Gauthier-Villars, Quai des Grands Augustins 55, Paris.
Collegium	Collegium	
Comptes-Rendus hebdomadaires des Séances de l'Académie des Sciences ..	Comptes rend.	

JOURNAL.	ABBREVIATION.	ADDRESS OF PUBLISHER.
Comptes-Rendus des Travaux de Laboratoire de Carlsberg Deutsche Zuckerindustrie ..	Comptes-rend. Trav. Lab. Carlsberg Deuts. Zuckerind. ..	H. Hagerup, Copenhagen. Verlag der Gesellschaft, Die Deuts. Zuckerindustrie, Berlin.
Electrician	Electrician	G. Tucker, Salisbury Court, Fleet Street, London, E.C.
Engineer	Engineer	S. White, 33, Norfolk Street, London, W.C.
Engineering	Engineering	C. R. Johnson, 35 and 36, Bedford Street, Strand, London, W.C.
Engineering and Mining Journal Färber-Zeitung	Eng. and Min. J. .. Färber-Zeit.	505, Pearl Street, New York City. Julius Springer, Monbijou-Platz 3, Berlin, N., Germany.
Foreign Office Annual Series (Cons. Reports)	F. O. Ann. Series ..	Wyman and Sons, Fetter Lane, London, E.C.
Gazzetta Chimica Italiana ..	Gazz. chim. ital. ..	La Direzione della "Gazzetta Chimica," Via Panis- perna, 89, Rome.
Gerber	Gerber	VI $\frac{1}{2}$ Gumpendorferstrasse 89, Wien, Austria.
Glückauf	Glückauf	Selbst-Verlag des Vereins für die bergbaulichen Interessen in Oberbergamtsbezirk, Dortmund, Essen (Ruhr), Germany.
Gummi-Zeitung	Gummi-Zeit.	Geschäftsstelle der "Gummi-Zeitung," Charlotten- strasse 6, Berlin, S.W. 68, Germany
Hopper-Seyler's Zeitschrift für Physiologische Chemie	Z. physiol. Chem. ..	Verlag von K. J. Trübner, Strassburg, Germany.
Imperial Institute Journal and Bulletin	Imp. Inst. J. or Bull. Imp. Inst.	Imperial Institute, London, S.W.
India-Rubber Journal	India-rubber J. ..	Maclaren and Sons, 37 and 38, Shoe Lane, London, E.C.
International Sugar Journal ..	Int. Sugar J... ..	N. Rodger, Office of "The Sugar Cane," Mossburn Buildings, Altrincham, Manchester.
Journal of Agricultural Science..	J. Agric. Sci... ..	University Press, Cambridge.
Journal of the American Chemical Society	J. Amer. Chem. Soc.	Dr. E. G. Love, 108, West 55th Street, New York City.
Journal of the American Leather Chemists' Association	J. Amer. Leather Chem. Assoc.	American Leather Chemists' Assoc., Easton, Pa., U.S.A.
Journal of Biological Chemistry..	J. Biol. Chem. ..	2427-9, York Road, Baltimore, Md., U.S.A.
Journal of the Chemical Society of London, Transactions and Proceedings	Chem. Soc. Trans. or Chem. Soc. Proc.	Gurney and Jackson, 10, Paternoster Row, London, E.C.
Journal of the Chemical, Metallur- gical, and Mining Society of South Africa	J. Chem. Met. Soc., S. Africa	F. Rowland, 5 and 8, Corporation Buildings, Rissik Street, Johannesburg.
Journal de Chimie Physique ..	J. Chim. Phys. ..	Gauthier-Villars, 55, Quai des Grands Augustins, Paris.
Journal of the College of Science, Imperial University of Tokyo, Japan	J. Coll. Science, Tokyo	Director of the College of Science, Tokyo Imperial University, Japan.
Journal of the Franklin Institute	J. Franklin Inst. ..	The Actuary, The Franklin Institute, Philadelphia, Pa., U.S.A.
Journal für Gasbeleuchtung und Wasserversorgung	J. Gasbeleucht. ..	R. Oldenbourg, Glückstrasse 8, München, Germany.
Journal of Gas Lighting	J. Gas Lighting ..	W. King, 11, Bolt Court, Fleet Street, London, E.C.
Journal of Industrial and Engineer- ing Chemistry	J. Ind. Eng. Chem... ..	C. L. Parsons, New Hampshire College, Durham, N.H., U.S.A.
Journal of the Institute of Brewing	J. Inst. Brewing ..	Harrison and Sons, 45, Pall Mall, London, W.
Journal of the Institution of Me- chanical Engineers	J. Inst. Mech. Eng. ..	Storey's Gate, Westminster, S.W.
Journal of the Russian Physical- chemical Society	J. Russ. phys.-chem. Soc.	Laboratoire de Chimie, Université Imperiale, St. Petersbourg, Russia.
Journal of Physical Chemistry ..	J. Phys. Chem. ..	W. D. Bancroft, Ithaca, N.Y., U.S.A.
Journal de Pharmacie et de Chimie	J. Pharm. Chim. ..	Imprimerie F. Levé, Rue Casette 17, Paris.
Journal für praktische Chemie ..	J. prakt. Chem. ..	J. A. Barth, Rossplatz 17, Leipzig, Germany.
Journal of the Society of Arts ..	J. Soc. Arts	G. Bell and Sons, York House, Portugal Street, London, W.C.
Journal of the Society of Dyers and Colourists	J. Soc. Dyers and Col.	E. T. Holdsworth, 10, Merton Road, Bradford, Yorks.
Leather	Leather	Leather Trades Publishing Co., 207A, Borough High Street, London, S.E.
L'Industria Chimica	L'Ind. Chimica ..	Associazione Chimica Industriale, Via Roma 28 (Galleria Nazionale Scale A), Turin, Italy.
Mémoriale des Poudres et Salpêtres	Mém. Poudres et Sal- pêtres	Gauthier-Villars, 55, Quai des Grands Augustins, Paris.
Metallurgical and Chemical Engi- neering	Metall. and Chem. Eng.	Electrochemical Publishing Co., 114-118, Liberty Street, New York City, U.S.A.
Metallurgie	Metallurgie	W. Knapp, Halle a. S., Germany.
Mining Magazine	Mining Mag.	819, Salisbury House, London, E.C.
Mining World	Mining World ..	Monadnock Building, Chicago, Ill., U.S.A.

JOURNAL.	ABBREVIATION.	ADDRESS OF PUBLISHER.
Mittheilungen aus dem königlichen Materialprüfungsamt zu Gross-Lichterfelde West	Mitt. k. Materialprüf.	Julius Springer, Mombijou-Platz 3, Berlin, N. Germany.
Mittheilungen aus der Centralstelle für wissenschaftlich-technische Untersuchungen	Mitt. Centralst. Wiss.-techn. Unters.	Prof. Dr. W. Will, Neu-Babelsberg, bei Berlin, Germany.
Mittheilungen des technischen Gewerbemuseums in Wien	Mitt. techn. Gew. Museums	IX/1, Hörlgasse 5, Wien, Austria.
Monatshefte für Chemie der kaiserlichen Akademie der Wissenschaften, Wien	Monatsh. . . .	K. Gerold's Sohn, Barbaragasse 2, Wien, I, Austria.
Moniteur Scientifique	Monit. Scient. . . .	Dr. G. Quesneville, 12, rue de Buci, Faubourg St. Germain, Paris.
Oil, Paint, and Drug Reporter..	Oil, Paint, and Drug Rep.	100, William Street, New York City, U.S.A.
Paper Making	Paper Making	5, Ludgate Circus Buildings, London, E.C.

ERRATA, 1909.

Issue.	Page.	Column.	Line from Top.	Line from Bottom	Errata.
No. 8—April 30	405	1	10	..	For "Sulphate" read "Sulphide."
" "	429	1	18	..	For "Bayard" read "Bagard."
No. 9—May 15	484	2	..	23	For "Tocum" read "Yocum."
No. 10—May 31	505	1	..	22	Add "See this J., 1903, 1103."
" "	507	1	23	..	" " See this J., 1906, 199."
" "	"	1	27	..	" " See this J., 1906, 1176."
" "	"	2	..	40	" " See this J., 1903, 1368."
No. 11—June 15	580	1	2	..	For "vendu" read "vendus."
" "	617	1	..	25	For "dihydroxy" read "trihydroxy."
No. 12—June 30	639	1	Foot note		For "37, 1158" read "38, 1158," and add "See this J., 1905, 326, 432."
" "	642	1	..	7	For "7902" read "4903."
" "	662	1	First abstract in Class XII.		For "turkey" read "duck" throughout.
No. 14—July 31	763	2	2	..	After "150°" insert "200°."
" "	763	2	Bottom line of table		For "above 372" read "above 572."
No. 16—Aug. 16	916	2	Title of patent		After "12,506" insert "of 1909; date of application."
No. 17—Sept. 15	934	1	29	..	For "air" read "hair."
" "	937	2	..	4	After "3189" insert "of 1909; date of application."
" "	948	1	1	..	This line should read "glyceroll, 12.47; alanine, 1.6; proline, 10.4; leucine, 4.2."
" "	948	1	3	..	For "oxyproline" read "oxyproline."
No. 18—Sept. 30	971	2	..	37	For "Willan" read "Wilbur."
No. 20—Oct. 30	1082	1	30	..	For "85°-87°" read "64°-65°C."
No. 21—Nov. 15	1127	1	..	24	For "Wienand" read "Winand."
" "	1136	2	..	10	For "1906" read "1909."
No. 23—Dec. 15	1233	2	Sixth line of Table IV.		For "4.47" read "6.47."
" "	1239	2	..	19	For "Diamond" read "Diamand."
" "	1241	2	7	..	For "930" read "830."
No. 24—Dec. 31	1297	2	39	..	For "1855" read "1734."

Journal of the Society of Chemical Industry.

No. 1, Vol. XXVIII.

JANUARY 15, 1909.

No. 1, Vol. XXVIII.

The Society of Chemical Industry.

Past Presidents.

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
†Walter Weldon, F.R.S.	1883—1884.
†Sir Wm. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt, LL.D.	1885—1886.
David Howard.	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook.	1890—1891.
J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
†Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
†E. C. C. Staford.	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer.	1895—1896.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Beilby, LL.D., F.R.S.	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinestein.	1901—1902.
Sir Wm. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.
Wm. H. Nichols, M.S., LL.D., D.Sc.	1904—1905.
Edward Divers, M.D., D.Sc., F.R.S.	1905—1906.
Eustace Carey.	1906—1907.
Sir Boverton Redwood, D.Sc.	1907—1908.

† Deceased.

LIST OF COUNCIL, 1908-1909.

President: Raphael Meldola, F.R.S.

Vice-Presidents:

Eustace Carey.	Walter F. Reid.
Dr. Edw. Divers, F.R.S.	A. Gordon Salamon.
Dr. J. T. Dunn.	Geo. C. Stone.
Prof. Percy Frankland, F.R.S.	Dr. T. B. Wagner.
A. R. Ling.	Chas. Wightman.
Sir Boverton Redwood.	R. C. Woodcock.

Ordinary Members of Council:

Prof. P. Phillips Bedson.	E. Grant Hooper.
Prof. W. Hodgson Ellis.	Dr. Charles A. Keane.
Oscar Guttman.	C. T. Kingzett.
H. Hemingway.	Frank H. Tate.
Prof. G. G. Henderson.	Dr. Leonard T. Thorne.
Prof. W. R. E. Hodgkinson.	Harold Van der Linde.

Sectional Chairmen and Secretaries:

Harry Silvester.	BIRMINGHAM.	F. R. O'Shaughnessy.
Dr. Milton L. Hersey.	CANADIAN.	Alfred Burton.
Max Muspratt.	LIVERPOOL.	W. Roscoe Hardwick.
Dr. J. Lewkowitsch.	LONDON.	Julian L. Baker.
—	MANCHESTER.	Julius Hübner.
C. J. Potter.	NEWCASTLE.	Dr. F. C. Garrett.
F. E. Atteaux.	NEW ENGLAND.	Alan A. Claffin.
Maximilian Toch.	NEW YORK.	Dr. H. Schweitzer.
Oliver Quibell.	NOTTINGHAM.	S. R. Trotman.
D. J. Playfair.	SCOTTISH.	Dr. Chas. E. Fawcitt.
Prof. J. A. Schofield.	SYDNEY, N.S.W.	T. U. Walton.
Prof. W. M. Gardner.	YORKSHIRE.	Thomas Fairley.

Honorary Treasurer:

Thomas Tyrer, Stirling Chemical Works, Stratford, E.

Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell, 59, Palace Chambers, Westminster, S.W.

Telegraphic Address: 59, Palatable, London.

Telephone Number: 715, Victoria.

THE JOURNAL.

Publication Committee:

The President.

Julian L. Baker.	J. Lewkowitsch, Ph.D.
J. Carter Bell.	A. R. Ling.
C. F. Cross.	W. Macnab.
Edw. Divers, M.D., D.Sc., F.R.S.	N. H. Martin.
T. Fairley.	B. E. R. Newlands.
Prof. A. G. Green.	John Pattinson.
H. Hemingway.	A. G. Perkin, F.R.S.
John Heron.	F. B. Power, Ph.D.
Prof. W. R. E. Hodgkinson, Ph.D.	Prof. H. R. Procter.
G. T. Holloway.	Sir Boverton Redwood.
E. Grant Hooper.	Walter F. Reid.
David Howard.	John Spiller.
Julius Hübner.	L. T. Thorne, Ph.D.
Charles A. Keane, D.Sc., Ph.D.	Thomas Tyrer.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

J. Allan XII.	O. F. Hudson X.
E. F. Armstrong, (XVI., XVII., Ph.D., D.Sc. (XVIII., XX.		A. T. Larter II., IV.
D. Bendix III.	R. Lessing, Ph.D. II., III., VII.
H. G. Bennett XIV.	A. G. Levy, B.Sc. VIII., IX.
E. Bentz IV., V., VI.	E. W. Lewis XIII.
J. O. Braithwaite XX.	G. W. Macdonald, M.Sc. XXII.
J. F. Briggs (XVI., XVII., XIX., XX.	F. Marsden, Ph.D. IV., V.
R. B. Brown IV., V.	C. A. Mitchell, (B.A.)	XII., XXII.

DR. LEWKOWITSCH IN THE CHAIR.

THE VISCOSITY OF INDIA-RUBBER AND INDIA-RUBBER SOLUTIONS: WITH SPECIAL REFERENCE TO ITS BEARING ON THE STRENGTH OR "NERVE" OF CRUDE RUBBER.*

BY DR. P. SCHIDROWITZ AND H. A. GOLDSBROUGH.

1.—PRELIMINARY COMMUNICATION.

(a) *Introductory*.—The present communication is a record of some preliminary experiments which were undertaken with a view (1) to studying the viscosity of india-rubber solutions; (2) to ascertaining whether there is any correlation between the viscosity of india-rubber (studied in solution) and its strength or "nerve" generally, and what the nature of such correlation may be; (3) to devising, in the event of the experiments under (2) resulting affirmatively, a method for the measurement of india-rubber "nerve" either wholly or partly by means of viscosity estimations.

Our preliminary experiments in this direction have so far proved satisfactory, inasmuch as they appear to indicate that there is a connection between the condition of the soluble rubber substance (as measured by the viscosity of its solution) on the one hand, and the "nerve" of the original crude rubber on the other hand.

We did not anticipate that the results which we might obtain by physical measurements on solutions of rubber could bear a direct relationship to the total "nerve" of the original crude rubber, because it appears to be beyond reasonable doubt that the "nerve" is at least partly due to the mechanical structure or texture, if we may so call it, of the material. It follows, therefore, and we believe that this has not been pointed out by any previous observer, that there are at least two main groups of factors to which the qualities summarised by the term "nerve" are due, namely that which we will, for convenience, call "mechanical" or "structural" "nerve," and that which may be termed "physical" or "chemical" "nerve."

(b) *The Viscosity of India-rubber Solutions*.—We have not been able in the literature of the subject to find any record of any determinations of an exact nature of the viscosity of india-rubber solutions. The instrument employed by us was an Ostwald capillary double bulb viscometer (Fig. 1) of the approximate dimensions:—Total height of apparatus, 24 cm. Capacity of Bulb A, 11 c.c. Capacity of Bulb B, 10 c.c. Length of capillary, 4.5 cm. Bore of capillary (approx.), 1 mm.

In the experiments made so far we have employed only one solvent, namely pure benzene, and the solutions examined have been of a relatively dilute nature, containing, as a maximum 1 to 1.5 per cent. of the solute. The standard temperature at which the experiments were conducted was 20° C.

The rubber solutions were prepared by weighing a definite quantity of rubber (generally one gm.) cut into very small pieces and exposing these to the action, at the required temperature, of a measured volume of solvent. After solution had taken place the sometimes bright, but occasionally turbid solutions were filtered through a plug of glass wool in order to remove mechanical impurities. In our earlier experiments in the cases in which solution appeared to be practically complete, the concentration of the solution was calculated from the quantity of rubber and solvent originally employed.† In our later experi-

FIG. 1.

ments—and this is the method which we now always employ—the actual quantity of rubber in solution was estimated by evaporating a known volume of the filtered liquid and weighing the residue. In the experiments conducted at the ordinary temperature of the laboratory the samples together with the solvent were placed in glass bottles, protected from the action of light and shaken (as little as possible) at regular intervals and in a regular manner.*

Series 1.—The rubbers examined consisted of six samples of *Funtumia elastica* (Nos. 1–5 and 7); three samples of *Hevea Braziliensis* from Eastern Plantations (Nos. 8, 9, and 10), and a sample of "Fine hard Para" (*Hevea E.* from Brazil).

The *Funtumia* samples 1–5 consisted of somewhat dark, but clear, corrugated sheets which appeared to be strong and normal in character. No. 1 was perhaps rather weaker than the others. No. 7 was a thin light brown sheet rubber, obviously of a somewhat abnormal character. None of the samples were "indigenous" rubbers; that is to say, they had all been prepared from fresh latex under skilled European superintendence. We are indebted for these samples to the Mabira Forest Company of Uganda. The general analytical figures, on analysis, were as follows:—

TABLE I.

	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.	No. 7.
Moisture	per cent. 0.50	per cent. 0.72	per cent. 0.61	per cent. 0.36	per cent. 0.34	per cent. 1.74
Resin .	7.59	7.41	7.69	8.18	9.60	6.79
Ash . .	0.41	0.66	0.43	0.52	0.64	1.22

Judging by our previous experience of *Funtumia* rubbers these figures are fairly normal, excepting that the resin in No. 5 is rather high, and in No. 7 rather low. The latter sample also contained a rather high percentage of ash. The three samples 8–10 were plantation *Hevea* "crêpes" (from Ceylon or Malaya) obtained on the London market. No. 8 was a greyish yellow, No. 9 of a light yellow, and No. 10 of a very pale cream colour. They were practically dry. The sample of "Fine hard Para" employed as a control—inasmuch as this variety of rubber is the standard of industrial quality—was of considerable age, and therefore, perhaps, not quite so satisfactory as a fresher sample might have been, but the reasons for

* Taken as read.

† It is possible that, for this reason, some of our earlier figures may be rather too low.

* Full details of the method of work, the limits and influence of temperature, &c., are reserved for a future communication.

using this particular specimen were (1) that it was practically dry, (2) that it had dried naturally, (3) that the dimensions of the clear, translucent layers were such as to make the cutting of test strips for the mechanical tests (*cf. infra*) a practical possibility. The amount of resin in the sample was rather high, namely, 3.46 per cent.

The following table shows the results of the viscosity determinations carried out with the rubbers described above.

TABLE II.

No. or mark.	Nature of rubber.	Concentration of benzene solution per cent.	Relative viscosity (benzene = 1).
1	<i>Euntamia elastica</i> (Corrugated sheet)	1.0	19.1
		0.5	5.3
		0.25	2.2
2	" "	1.0	35.3
		0.5	7.6
		0.25	2.7
3	" "	1.0	27.3
		0.5	6.1
		0.25	2.5
4	" "	1.0	37.0
		0.5	7.2
		0.25	2.7
5	" "	1.0	37.6
		0.5	7.8
		0.25	2.9
7	(sheet)	1.0	16.6
		0.5	2.9
		0.25	1.6
8	Plantation <i>Hevea</i> (crepe)	1.0	6.7
		0.5	2.7
		0.25	1.6
9	" "	1.0	9.3
		0.5	3.3
		0.25	1.6
10	" "	1.0	9.1
		0.5	3.1
		0.25	1.7
Fine hard Para	Brazilian <i>Hevea</i>	1.2	40.6
"	" "	1.0 (calculated)	26.2
"	" "	0.55	7.1
"	" "	0.24	1.7

Of considerable interest in the above table are the very low figures shown by the plantation *Hevea* specimens as compared with the Brazilian *Hevea* and the *Euntamia* specimens. Graphically represented (Fig. 2) the results are still more striking. No. 7, which was known to be of a somewhat abnormal character, gives an abnormal curve.

The flat nature of the curves shown by Nos. 8–10 as compared with the other rubbers induced us to make an attempt to ascertain the comparative strengths of these typical samples by some direct physical method. If the rubbers had been in homogeneous sheet form, this would have been a comparatively easy matter, but as it is obviously impossible to cut strips for tension experiments from corrugated sheet or "crepe," some other expedient had to be adopted.

The method employed by us was to dip strips of "quantitative" filter paper 60 by 10 mm. into 1 per cent. benzene solutions of the rubbers, to allow the strips to dry and then to ascertain the breaking strain. The figures obtained were as follows, the results denote grams and in each case represents the mean of a number of determinations:—

No.	Breaking strain.
Paper alone (undipped).....	700
Rubber No. 1.....	950
" No. 8.....	860
" No. 10.....	860

The results, naturally, can only be regarded as a rough approximation, but they serve to indicate that there is a connection between the viscosity curves and the strength of the rubbers in question. The increased strength imparted by the relatively viscous rubber No. 1 to the paper compared with that imparted by the rubbers of low viscosity (8 and 10) is roughly as 25 : 16.

Further confirmation of the connection between viscosity and strength in these particular samples was afforded by considerations of a purely empirical, though to some extent of a highly practical nature. In brief, Nos. 8–10 were decidedly brittle or "short," whereas the other rubbers gave satisfactory indications in response to the crude but by no means useless "hand-pulling" test.

Nature of the viscosity curves.—It will be observed, on referring to Fig. 2, that beyond a certain viscosity, the

FIG. 2.

curves become straight lines. This was confirmed by subsequent experiments. If, for the sake of convenience, the point at which the curve becomes a straight line, is termed the *critical point*, it follows that for all readings above the critical point, the viscosity is directly proportional to the concentration. If it were found, on producing the part of the curve above the critical point downwards, that all the straight lines thus produced met in a common point, it would follow, taking the viscosity of the rubber itself as equal to that of a 100 per cent. solution, that the viscosities of different rubbers would be inversely proportional to the concentration of the solutions at a fixed viscosity above the critical point and *vice versa*. This, however, is not the case, and the conclusion which, we think, is of some importance, is that although for any given rubber the viscosity of a solution (naturally at a fixed temperature) is proportional to the concentration at any given point above the critical point, yet the viscosity of the rubber itself cannot be ascertained by reference to such a point, and consequently the viscosities of two rubbers cannot be compared by ascertaining the viscosities of their solutions at a fixed concentration.

In order to compare different rubbers in regard to their viscosity we took two points (above the critical point) on each curve, and, inserting the values successively in the linear equation, $y = mx + c$, (where x = concentration and y = viscosity), obtained m and c . By inserting m and c in the equation where $x = 100$, we obtained y , the viscosity of a 100 per cent. solution—i.e., of the rubber.

The error involved in this method of calculating viscosity is, we think, small, provided that the concentration of the solution examined is ascertained with accuracy. Assuming that the concentration is in the neighbourhood of 1 per cent., at least 50 c.c. of the solution should be taken for the determination of the quantity of the rubber contained.

The values calculated by this method for Nos. 1–5 and “Fine Para” were as follows:—

No.	Viscosity (benzene = 1.0).
1	4966
2	8946
3	7551
4	9343
5	9940
Fine Para	7253
8	1000 (approx.)
9	1400 ..
10	1400 ..

It is obvious from the curve why the values for Nos. 8, 9, and 10 could not be calculated. It is probable that if we had been in a position to obtain readings at higher concentrations this might have been done. With regard to these three rubbers, we were not satisfied that we had reached the critical point, and we were unfortunately not in a position to determine the viscosities at higher concentrations. In any case it is quite obvious that the values for these three specimens must be very low.

Second series.—This series consisted of three rubbers concerning which the origin, nature, and age of the trees (at the time of tapping), were accurately known. In addition, the specimens were all in sheet form, and ordinary tension experiments could therefore be applied and the results compared with the viscosity numbers and the “practical” opinion concerning their quality.

With regard to the “nerve” or strength of these rubbers judged by the ordinary method of pulling by hand, the remarks were made that A was rather lacking in strength, B was fairly strong, and C was very strong.

Viscosity experiments.—The numbers obtained with specimens A, B, and C were as follows:—

TABLE III.

Mark.	Ceylon <i>Hevea</i> rubber.	Concentration of benzene solution per cent.	Relative viscosity of solution (benzene = 1).
	Age of tree, years.	per cent.	
A	8	0.86	6.6
		0.43	2.6
		0.21	1.5
B	6–13	1.00	21.4
		0.50	5.2
		0.25	2.2
C	30	1.00	32.3
		0.50	6.8
		0.25	2.5

The results obtained are shown graphically in Fig. 2. The most interesting feature of the figure is the very flat nature of curve A as compared with B and C.

By calculation (*cf. supra*) viscosity values for the actual rubbers (*i.e.*, of 100 per cent. solutions) were obtained as follows:—

Mark.	Viscosity of rubber (benzene = 1).
A	1250 (approx.)
B	6653
C	8843

Tension experiments.—Strips of a cross-sectional area as nearly as possible 40 sq. mm. and sufficiently long to

allow a distance of 30 mm. between grips, were cut for rubbers A, B and C, and for comparative purposes also from the sample of “Fine Para” referred to above. The strips were then broken in a vertical, direct pull machine,* the breaking strain and elongation at break being observed. The units taken were: for the breaking strain, grams per sq. mm. of cross-sectional area; for the elongation, the original length of the strip between lines drawn between the grips. Each figure represents the average of a number of determinations. A second series of experiments was made with similar strips in order to determine the minimum weight per unit of cross-sectional area which would, under certain conditions, cause a permanent distension of the material. The figure so obtained we call the “co-efficient of resiliency,” although possibly a better term might be “limit of elasticity.”

The results of the tension experiments will be found below in Table IV. We have added the details concerning the nature, &c., of the rubbers and also the viscosity figures, so that a comprehensive view of the whole results in regard to Series II. may be obtained.

TABLE IV.

Mark.	<i>Hevea</i> rubber.	Elongation at break	Break ing strain,†	Co- efficient of resi- liency,‡	Vis- cosity (benzene = 1).
A	Ceylon, from 8 year old trees, weak.	4.5	58	21.6	1000 (approx.)
B	Ceylon, from 6–13 year old trees, fairly strong.	8.0	52	24	6653
C	Ceylon, from a 30 year old tree, very strong.	9.75	218	57	8843
Fine Para	Brazilian, fair, but old specimen.	10.0	406	75	7253

† Grms. per sq. mm. of cross-sectional area.

The general superiority of C and the Brazilian specimen over A and B is obvious. The inferiority of B is not so marked, however, in regard to viscosity as with respect to the other factors, and we suggest that it is possible that we have here a case where a rubber is relatively weak as regards its mechanical structure, but fairly satisfactory with respect to the chemical or physical structure of its mass. It will be noticed also, that whereas C is inferior to the Brazilian specimen with regard to breaking strain and resilience, that its viscosity is superior to that of the latter. We think that in the case of the Brazilian product there is not the slightest doubt that a considerable proportion of its mechanical strength is due to purely mechanical causes, and that comparing it with C, the viscosity figures are probably a better criterion of the relative “nerve” of the actual rubber substance of the two specimens than the tension results.

Another point of interest is that the specimen A, which is inferior to B in every other respect, shows a rather higher figure for breaking strain. We think the explanation of this point is not far to seek. This specimen (A) contained a good deal of insoluble matter, and experience has led us to know that the presence of a certain type of insoluble matter in rubbers indicates that they have gained somewhat in toughness at the cost of elasticity and resilience. In such cases the breaking strain may be comparatively high, but the elongation and resilience are always low. We have referred above to “a certain type” of insoluble matter, because it appears to us that it is necessary to differentiate between the insoluble matter present in old or exposed rubbers which is probably an oxydation or hydration product,‡ or a mixture of both,

* We may add—although this does not apply to the experiments here recorded—that we have in our most recent work discarded, for general work, tension apparatus of the ordinary “grip” type, as we have found that more accurate and rapid results may be obtained with the new Schopper apparatus, in which a ring shaped test body (obtained by double punching) working over revolving rollers is subjected to vertical tension by means of hydraulic power.

‡ Weber, “The Chemistry of India-Rubber,” pp. 7–12, and Spiller, J. Chem. Soc., 1865, 44.

and the insoluble matter present in the fresh "hard cure" Brazilian *Hevea*, which according to Spence* consists mainly or largely of fibrous proteid substance. The insoluble matter to which we have referred in connection with sample A shows the characteristics of the former and not of the latter variety. We may also call attention to the fact that the viscosity figures for A, B, and C are in accord with "practical opinion" regarding the relative strength of these three specimens. At the same time, we do not wish, before having accumulated further data, to lay any undue stress on the fact, nor should we be justified in concluding at all positively that the differences observable are due primarily to the relative ages of the trees from which these rubbers were obtained. It is an undoubted fact that the method of coagulation† plays an important part in connection with the question of "nerve," and that variations in the quality of latices obtained from trees of the same species may be due to other causes than that of age.

Meeting held at Burlington House on Monday, Dec. 7, 1908.

DR. LEWKOWITZ IN THE CHAIR.

THE STRUCTURE OF CRUDE INDIA-RUBBER.

BY PHILIP SCHIDROWITZ, PH.D.

Preliminary Note.

According to W. B. Hardy‡, "common black india-rubber" in sections cut with the freezing microtome displays the structure common to many organic gels, namely, that of an open net or fine open sponge. Now, the ordinary "black india-rubber" of commerce is vulcanised rubber, and it is therefore a little difficult to know whether Hardy referred to ordinary black vulcanised rubber or to some particular variety of black crude (i.e., unvulcanised) rubber.

Apart from this "open net" structure, which may or may not be an attribute of the crude variety¶, it has been assumed that the main substance of ordinary crude, dry india-rubber is a structureless mass§, and that after coagulation has taken place, and certainly after the coagulated rubber has become dry, that the original globular condition of the rubber particles as seen in the latex disappears; indeed, there has been a serious discussion as to whether the globules in the latex were actually rubber or some substance which, at the moment of coagulation, polymerises into the rubber hydrocarbon.¶ after the globules containing it have first burst their envelopes and discharged their contents. I have found from observations made on two different species, namely, *Hevea Brasiliensis* and *Funtumia elastica* :—

* *Loc. cit.*

† Schidrowitz and Kaye, *India-Rubber Journal*, 23rd Sept., 1907, and V. Henri, *loc. cit.*

‡ *J. of Physiology*, 24, 169.

§ I have not been able to observe "net" structure in films of crude rubber obtained either (a) by squeegeeing on to a slide solid rubber softened with a solvent; (b) by evaporating off the solvent from a benzene solution; (c) or by coagulating a film of latex between a slide and cover glass; but it is possible that microtome cut sections might show the structure referred to. If, however, a film, obtained by evaporating off a few drops of a 1 per cent. benzene "solution" on a slide, is subjected to the action of a dilute solution of sulphur chloride in benzene (1:100) for a few seconds, I have found that (after removing excess of the reagent by means of acetone, and subsequent drying, a pronounced net structure is formed. If the treatment with sulphur chloride is continued for some minutes, the net structure becomes much more pronounced and presents a really remarkable appearance. Whether this net formation is an essential or an accessory feature of the process of "cold curing"—as vulcanisation with solutions of sulphur chloride is termed technically—or of vulcanisation in general, is a matter well worth investigation, and I propose to do so in the future.

¶ Cf. Weber, "The Chemistry of India-Rubber," p. 17, and D. Spence, *Inst. Comm. Research in the Tropics*, J., No. 13, 1907. Weber, *Ber.*, 1903, 36, 3108—3115; *Gummi-Zeit.*, 19, 161—164; A. W. de Jong and W. R. Tromp de Haas, *Ber.*, 1904, 3298—3301; Each and Chwolson, *Gummi-Zeit.*, 19, 165—166, &c.

(1) That if a thin preparation* of transparent dry rubber is examined under the microscope with magnifications of about 900 and upwards, it is seen to contain very numerous globules, similar in appearance and size to the globules present in the latex.

(2) That if such dry rubber is dissolved in benzene (cf. preceding communication) and examined in solutions of 1 to 5 per cent. strength with reflected light by means of the Leitz dark ground illumination and parabolic condenser, that is to say, on the principle of the ultra-microscopic method, the "solutions" are seen to contain numerous globular particles, these again being similar to those present in the latex.

(3) That if a drop of such a benzene "solution" is allowed to evaporate on a slide, the resultant film presents much the same appearance as a drop of diluted and dried latex, or of a drop of diluted latex coagulated by suitable means, the only difference being that the reticulated structure is not visible to any marked extent. The globular particles are, however, visible in large numbers in every case.

(4) That if a drop of diluted (*funtumia*) latex is coagulated by means of heat between two cover-glasses, the reticulation is seen to consist of branches of more or less structureless matter in which chains of and single globules are enmeshed in large number.

In connection with the films obtained by squeegeeing or from "solutions," those which were quite transparent showed the globules less distinctly than those which were slightly opaque. When, however, such a transparent film is touched or irritated with a glass rod or otherwise, the portions touched become less transparent, and at the same time the globules appear much more sharply defined. When a clear film, showing the globular structure somewhat imperfectly, is treated with a dilute sulphur chloride solution, the resultant preparation, in addition to showing very pronounced "net" structure, exhibits the globules distinctly. Such preparations are slightly opaque. It is possible that the clear film is an approximation to a solid solution of the globules, the opaque film to an irreversible gel.

In conclusion, then, it appears that the globules are not destroyed by coagulation of the latex, but that they continue to exist in the dry rubber and are not removed even by "solution" in benzene.

I take this opportunity of expressing my thanks to Messrs. Leitz for placing at my disposal some of the special optical instruments necessary for this work.

* Note.—The methods employed for obtaining preparations were:—(1) Squeegeeing a thin (hand cut) section on to a slide after softening with chloroform; (2) evaporation of a few drops of a benzene solution, so forming a film; (3) a homogeneous strip was punched from a very thin transparent sheet. This strip was then drawn out until very thin, and a part fixed, while under tension, on to a slide by means of shellac.

Meeting held at Armstrong College on Thursday, Dec. 10, 1908.

MR. C. J. POTTER IN THE CHAIR.

CHEMICAL CHANGES IN PORTLAND CEMENT CONCRETE, AND THE ACTION OF SEA WATER THEREON.

BY CHARLES J. POTTER.

Some years ago the failure of the Portland cement concrete in a dock was brought to my notice; the work had stood well in the sea water for two or three years after completion, after which the walls commenced to show signs of failure, the concrete turning quite soft in places and showing great expansion, and this serious action went on so rapidly that reconstruction was necessary. This failure and several others of a similar nature induced me to make experiments to try and find out the cause with the hope that I would be able to discover some method of prevention.

I commenced my experiments by moulding small blocks of concrete made with three parts of sand to one part of cement, and after these were set, I immersed one of each in strong solutions of the various salts which are found in sea water; I soon found that the magnesium salts were the cause of the mischief, and that the quarter per cent. of magnesium sulphate found in sea water was the most active, as blocks in a strong solution burst up in a few weeks. The magnesium chloride had a tendency to soften the blocks but without showing any expansion. Calcium sulphate had a softening action, but it was slow as compared with magnesium salts.

Since I commenced these experiments, Mr. J. Pattinson, Dr. Michale Chatelier, and several other experts have written articles on this subject, and there can now be no doubt that the damage is caused by the magnesium salts in the sea water acting on the feebly combined lime and alumina in the cement concrete and forming calcium sulphate and alumina compounds, which on taking up water of crystallisation do the bursting of the concrete.

We may take it that Portland cement concrete is composed of cement, sand, gravel or small stones, and larger stones. I term the mixture of sand and cement the mortar of the concrete, and if in this mortar the proportion of sand to cement is too high, then the cement will be unable to fill up all the interstices of the sand, and this mortar when set will be porous; also if this mortar is unable to fill up all the spaces between the stones then the concrete will be open.

In the case of the dock failures which I have referred to, the mortar in the concrete was 4 sand to 1 cement, and the concrete was rather open. Mortar of this proportion is very porous, so with each rise and fall of the tide fresh doses of magnesium sulphate would be brought in contact with the cement, which no doubt accounts for the rapid destruction of these works.

Within the last few years these failures have not been so common, as engineers appear to be doing their utmost to get their cement mortar tight, and this is just a matter of experiment with the class of sand that is being used. A few open spaces in the concrete are of much less importance than porous mortar.

In making concrete it is most important that the cement and sand should be thoroughly mixed, and there can be no doubt that mechanical concrete mixers are a great safeguard as compared with the old method of hand mixing. If any mistakes are made in the proportions of cement used the chances are that it will not be too much cement that is added.

If the above precautions are carefully carried out the action of the sea water on the concrete should be reduced to surface action only; but there appears to me to be a danger in this surface action and it may be only a matter of time for mischief to begin to show even in the most carefully constructed works. The sea water will not miss chances of finding out weak places.

My method of guarding against this danger was to add something to the cement clinker while grinding it, which would, after the concrete is set, get a firm enough hold of the lime in the cement to prevent the magnesium salts in the sea water from acting on it. I tried various materials in various proportions, such as burnt slints, clinkers, slag, burnt fire clay, pozzuolana, trass, and burnt red brick clay. I got the most promising results from the last and found that the temperature of calcination was a most important feature. After numerous experiments I came to the conclusion that the addition of six parts by weight of calcined clay to ten parts of cement gave the best all round results for practical work. Very thorough and intimate mixing and fine grinding were absolutely necessary.

Now let me refer to the results of my tests of Portland cement as against this red clay cement, or red cement as I call it. The Portland tests are the average of many different brands of best quality cement, a number of them from the Thames and Medway. The red cement tests are the average of a number of samples and maximum and minimum in both cases varied but little from the general average.

The test briquettes were all put into water (salt or

fresh) 24 hours after moulding, and remained in the tanks until they were tested. The fresh water tank was emptied and re-filled every three months. The salt water tank was filled with water taken from the River Tyne at high tide, which is equal to sea water, and as a number of briquettes soon precipitated the small quantity of magnesia found in salt water this tank was emptied and re-filled once a month. Both Portland and red cement tests were treated in exactly the same way.

A second series of salt water tests was placed 24 hours after moulding in a perforated box half way between high and low tide in the River Tyne. These tests were started four years later than the tank tests, so they only go up to six years.

A third series of tests was placed in salt water to which had been added ten per cent. of magnesium sulphate; this solution is about 40 times stronger than sea water. It is a very severe test, as it gives results at a few weeks which may take as many years to show in salt water. This test was of great assistance to me in carrying out these experiments.

The diagrams give on the vertical scale the average breaking strain in lb. per square inch, and the horizontal scale gives the age of the briquettes when broken, commencing at one week and going on up to 10 years. The breaking area of all the briquettes on the diagrams was one square inch, but some of the tests were also carried on in duplicate with $1\frac{1}{2} \times 1\frac{1}{2}$ briquettes = 2½ square inches, but strange to say these larger briquettes did not appear to have any appreciable effect on the results. All the sand used in these tests was standard cement testing sand which all passed through 20×20 and stopped on 30×30 sieves. Proportions of sand to cement were all taken by weight.

Diagram No. 1 shows neat Portland cement as against neat red cement in fresh water. The Portland (dotted line) commences at 435 lb. per square inch at one week and goes on steadily improving up to ten years, and this points to the Portland cement selected for these experiments being of thoroughly good quality for fresh water work. The neat red cement (full line) only stands 230 lb. at one week but goes on improving steadily up to 540 lb. at ten years. So neat Portland is stronger than neat red at all these dates in fresh water.

DIAGRAM NOS. 1 AND 3.

No. 2 Diagram shows neat Portland against neat red in salt water tank. The Portland commences at 400 lb. one week, reaches 500 lb. at twelve weeks, after which it goes gradually back to nil at five years. Most of these bricks showed surface blisters at or before one year, followed by great expansion and bursting up at later dates; the fractures showed signs of internal strain as they were so very uneven. The fracture colour was a dirty green, quite different from the fresh water bricks, and when dried these fractures showed a dirty white colour due to precipitated magnesia within the briquettes.

The salt reds start at 280 lb. at one week, come up to the Portland at eight weeks, reach 640 at two years, and go on improving a little up to six years, when no more tests were left.

No. 3 Diagram shows Portland 3 to 1, and red 3 to 1 in fresh water. For the first twelve weeks, the reds are a little below the Portlands, after which they are practically equal, each 500 lb. at ten years.

No. 4 Diagram gives 3 to 1 Portland and red in salt water tank. Here we have the Portland a little above the

DIAGRAMS NOS. 2, 4, and 5.

red for three weeks, after which the Portland finishes at ten years a little under 400 lb., as against the red 580 lb.

Diagram 10 gives Nos. 1 to 4 on one sheet so that they may more easily be compared. On this diagram the salt tests are full lines and the fresh are dotted.

The red tests are all higher in salt water than in fresh, and the Portland are all lower in salt than in fresh. This points to the red liking the salt water better than the fresh and just the reverse with the Portland.

The next diagram, No. 5, shows 5 of sand to 1 cement in salt water tank. These briquettes are very porous and, when lifted out of the tank, a considerable amount of water filters out from them. The Portland stands 60 lb. at one week, goes up to 160 at one year and falls back to *nil* between five and six years; the red commences much the same as Portland, but reaches 250 at one year and goes on improving up to nine years, when the tests were exhausted.

No. 6 Diagram gives the sea water tests when the briquettes were placed in the perforated box in the river, halfway between high and low tide. This appears to be a much more severe test to the Portland than leaving them in the sea water tank, as the 3 to 1 Portlands com-

menced to fall at two years and go steadily down up to six years, but the red stands 320 at one year and goes up to 460 at six years. Portland, 5 to 1, shows *nil* at five years as against red 360 at six. There are more of this series left, but they are not yet due to test at seven years. I have had these tests independently carried out up to three years by Mr. Faija, and his tests give very similar comparative results to mine, but his results were all higher than mine, owing I believe to using a little less water in the moulding of the briquettes and hammering into the moulds, which was not usual ten years ago.

No. 7 Diagram shows tests of briquettes which, 24 hours after moulding, were immersed in a tank of sea water to which had been added 10 per cent. of magnesium sulphate. The vertical lines on this diagram represent months. The neat Portland goes up to over 500 at one month but goes rapidly back to *nil* at one year. The

DIAGRAM NO. 7.

red as usual neat commences low at 250, but goes on improving up to two years. One of these briquettes has recently been tested; at eight years it stood 1015 lb., but there were signs of damage to the outer surface of this briquette, only giving about 1 16th in. all round. At the bottom of the diagram the 3 to 1 solution tests are shown—*nil* at eight weeks for the Portland, but the red reaches 260 at 12 weeks and finishes the two years over 300. Some large blocks 4 ft. by 12 in. by 6 in. were placed in the river ten years ago; the 5 to 1 Portland went to pieces in four to five years. 3 to 1 showed signs of damage at about eight years and is getting bad now, but the 5 and 3 to 1 reds are still both quite sound.

All these tests show better results with red cement in salt water than in fresh, and I am unable to account for this. Portland cement contains over 60 per cent. of lime; red under 40; so there is much less lime in red

DIAGRAM NO. 6.

than in Portland for the sea water to act upon, and the high long date red tests point to the silica in the calcined clay combining with the lime.

A 1 to 1 mixture of cement and calcined clay equal to only 30 per cent. of lime, gave high tests at long dates, but the early date tests were too low for practical work. As already mentioned, fine grinding for red is necessary, but extremely fine grinding did not appear to improve the tests. All these tests show a very large proportion of surface to volume, as the briquettes are very small and the larger blocks last referred to stood longer in the river than the 1 inch by 1 inch briquettes did. In the case of a thick dock or quay wall, the proportion of surface to volume is very small, and my tests can have no relation to the probable life of these massive walls, assuming of course that they are not porous and open. But in the case of ferro-concrete piles, which are frequently 18 in. and sometimes only 15 in. square, the proportion of surface to volume is very large and all my tests point to extra danger in this class of work.

If concrete shows white slimy matter (which is magnesia) coming out, then mischief is going on inside. If a chipping from a wall shows the dirty green colour, this points to surface action.

I next wish to refer to the action of carbon dioxide on Portland cement concrete; my attention was drawn to this in the following way:—I had occasion to fix some perforated tiles in a malt kiln which would have to stand a temperature of over 200 F., and decided to try a mortar of 3 sand to 1 of very fine cement. The fumes passing through the tiles and coming in contact with the cement were from an open coke fire burning with an excess of air, and so contained an ample supply of carbon dioxide. Some months after these tiles were fixed a few of them were broken through an accident, and I then noticed how very hard this cement mortar was. I had this examined and found that it contained no combined water, but a very large quantity of carbon dioxide. Set cement generally takes up some 10 per cent. of combined water at early dates, more or less according to the fineness of grinding, so all this water must have been replaced by carbon dioxide. To carry this further I made up a number of 3 to 1 briquettes and after a few days in water took them out and placed them in a box charged with pure carbon dioxide. The briquettes rapidly warmed, gave off water and created a partial vacuum in the box. For the first few hours the carbon dioxide could not be passed fast enough into the box to satisfy the demand. The tests of these were about double the average tests of wet briquettes of the same age, and only a trace of combined water was left in them after being six months in this box. This points to the chemical combination of lime, silica, alumina, and water in set cement being very feeble, and perhaps accounts for the magnesia in sea water being so easily able to act upon the lime.

Carbonating makes cement lighter in colour; it cannot get more than 1/16th inch into neat cement, but it filters its way into 3 and 5 to 1 mixtures, and it is interesting to examine the fracture of briquettes that have been so treated, as a glance tells how far the action has gone in. I carried these experiments further by putting some of the carbonated briquettes into the strong solution already referred to.

Diagram No. 8 gives the results of these tests, both Portland and red, all 3 sand to 1 cement.

DIAGRAM No. 8.

Carbon dioxide and solution tests.

- 1st Series.—Remaining in carbon dioxide up to breaking period.
2nd Series.—Remaining in carbon dioxide for 9 days then immersed in sea-water solution until breaking period.
3rd Series.—Remaining in carbon dioxide for 12 months then immersed in sea-water solution until breaking period.
4th Series.—Remaining in an ordinary dry atmosphere (test house) for 12 months then immersed in sea-water solution until breaking.
5th Series.—Remaining in a perfectly dry enclosed atmosphere (lime-dried) for 12 months then immersed in sea-water solution until breaking.

Table of tensile tests of above.

Results in lbs. per sq. inch when tested at three years from date of making.

3 to 1 tests.	1st series.	2nd series.	3rd series.	4th series.	5th series.
Portland	719	415	910	760	nil
Red	750	690	1120	840	360

1st series: Kept in carbon dioxide for three years, then treated. These tests are very high. 2nd series: Only nine days in carbon dioxide box, then up to three years in solution. 3rd series: Twelve months in carbon dioxide, then two years in solution. Thoroughly carbonated. 4th series: Twelve months in ordinary dry air test room, then two years in solution. Gas burning in the test room would make the carbon dioxide a little higher than in the atmosphere, but these were not thoroughly carbonated. 5th series: One year in a sealed box with burnt lime in it to take up all the water and carbon dioxide, then put into solution. The Portland went wrong in a very few weeks, but the red stood quite a nice test at the three years. These first four tests all point to Portland cement being absolutely proof against the action of sea water if thoroughly carbonated. No. 4 series points to the advantage of keeping cement concrete blocks used so much for pier work, and ferro-concrete piles, as long as possible in the air before putting them into sea water. In the case of dry docks, the construction of which generally occupies over a year, it may be that the effect of the carbon dioxide in the air on the walls is a most important factor in assisting them to resist the action of the sea water to which they will afterwards be subjected.

No. 9 diagram gives some results of tests after being in the malt kiln. These are also interesting, but I am inclined to think that the sulphur coming from the burning coke did some mischief to the tests up to three years.

DIAGRAM No. 9.

Malt kiln tests.

TEST BRIQUETTES when 24 hours old were put into an enclosed atmosphere over a coke fire and afterwards tested.

3 to 1.			5 to 1.			
Age of briquettes in weeks.		years.	Age of briquettes in weeks.		years.	
4	2	3	4	1	2	3
337	470	528	175	185	360	300

OTHER BRIQUETTES taken out of atmosphere at stated periods, kept in solution, and then broken as follows:—

Weeks in malt-kiln atmosphere.	3 to 1.			5 to 1.		
	Years in solution.			Years in solution.		
	1	2	3	1	2	3
4 weeks	—	487	505	120	—	—
8 "	—	565	660	—	—	—
12 "	—	900	—	147	150	150
52 "	640	720	575	—	—	—

I can carry these tests on to much longer dates, in particular those in the salt water box in the river, but it appears to me that they have gone on long enough to prove without doubt that the addition of the calcined clay is a most valuable safeguard against the action of sea water in concrete, the long date sand tests all being so high and the 5 to 1 porous briquettes all standing so well both in salt water and in strong solution.

DIAGRAM NO. 10
Comparative Tensile Tests Red and Portland in Salt and Fresh Water.
 Salt Tests— Fresh Tests—
 Red Cement NEAT TESTS. Portland Cement.

Portland cement appears to need a lot of carbon dioxide to make it safe. Red can take a little, but can quite well do without it. Over five thousand tons of red cement have already been used in various works in both sea and fresh water, and the results have been very satisfactory. When mixed with water this concrete is more plastic and sticky than Portland and appears to answer better for under water work. As a substitute for lime mortar for setting bricks it is liked, and the colour of the walls is pleasing to the eye.

Red cement reduces the cost of concrete work, and if it is going to lengthen the life of important and costly marine works, then my time and that of my staff which has been devoted to this subject, will not have been wasted.

It is necessary for me to state that my firm have protected this improvement in order to guard them against unintentional infringement.

DISCUSSION.

Professor HENRY LOUIS asked whether the author had made any analyses of the cements before and after exposure to the action of sea water; the great resistance of the "red cement" suggested that the lime was very rapidly converted into an insoluble silicate. He thought that valuable information might be obtained by a study of the micro-structure of the concrete, and asked if Mr. Potter had any information on this point. He also asked whether any compression tests of the briquettes had been made.

Dr. DUNN considered the Chairman's paper of great interest from a scientific as well as a technical point of view. The deterioration of cement by sea water, when that occurred, had been clearly shown to be due to the reaction upon it of the magnesium salts in the water. His partner, Mr. John Pattinson, had analysed in 1887 a number of samples from the Aberdeen graving dock, which, opened in 1885, was only a couple of years afterwards in a very bad condition through bulging and expansion of the outer walls and consequent leakage. While the briquettes made from the original cement contained on the average 53 per cent. of lime and under 1 per cent. of magnesia, the cement from the deteriorated concrete showed in no case more than 45, and in one as little as 17 per cent. of

lime, while the magnesia was always more than 4, and rose as high as 22 per cent. Direct experiments in which sea water was made to percolate through briquettes of cement and sand also showed that, while in the briquette the lime was diminished and the magnesia increased by the operation, the lime-content of the water was increased and its magnesia-content diminished. The lime in the cement obviously behaved towards these magnesium salts as though it were present as caustic lime; and in order to render the cement inert to sea water it clearly seemed necessary to convert the lime into some other form of combination. This Mr. Potter seemed to have accomplished, both by his carbonating experiments, and in the production of his "red cement," where no doubt the formation of a complex silicate had proceeded. It would be interesting to know whether Mr. Potter had made analyses of his samples, and if so whether these analyses indicated the formation of such compounds as are suggested.

Mr. POTTER in reply said that no chemical analysis had been made of the briquettes after they had been tested. With regard to compression tests, a series was now being carried out, but they had not matured sufficiently to be of any immediate value. Ten years ago compression tests were very unusual and were not as reliable as they were at present.

Meeting held at Glasgow on Tuesday, December 8th, 1908.

MR. D. J. PLAYFAIR IN THE CHAIR.

THE ESTIMATION OF SULPHIDE IN ALKALI CYANIDE.

BY THOMAS EWAN, M.Sc., Ph.D.

Several different methods of estimating the small quantities of sulphide which are usually present in potassium and sodium cyanides have been used, which do not always give concordant results. The following

notes contain the results of experiments which have been made from time to time during the past five years in order to discover the nature and magnitude of the errors of the different methods.

In the method which has been in use in the laboratory of the Cassel Cyanide Company for many years, 10 grms. of the powdered cyanide are dissolved in a small volume of water and a solution of lead nitrate is run in from a burette until a drop of the liquid when brought into contact with a drop of the lead nitrate solution, on blotting paper, no longer gives a brown stain. The end point is quite distinct and, provided the test is always carried out in the same way, the results are very concordant. They depend, however, very much on the quantity and quality of the water used to dissolve the cyanide. The following tests, which were all made with the same sample, show this clearly.

TABLE I.

Apparent percentage of potassium sulphide.			
C.c. of water to 10 grms. cyanide.	Unboiled water.	Boiled water cooled in air.	Boiled water cooled in coal gas.
10	0.036	0.0355	—
20	0.029	0.033	0.0355
40	0.025	—	—
50	—	—	0.0275
60	0.0185	—	—
80	0.006	—	—

With 120 c.c. of unboiled water the first few drops of lead nitrate solution gave a brown coloration, which disappeared again before the titration could be finished.

The apparent percentage of potassium sulphide is calculated on the assumptions that the whole of the lead used is present in the precipitate and that the precipitate contains lead and sulphur in the ratio required by the formula, PbS . The first assumption appears to be justified, because a solution in which a titration has been made gives (after filtration) no coloration when sodium sulphide is added to it. The second was tested by collecting and analysing a considerable quantity of the precipitate formed under the conditions of the test; the atomic ratio of sulphur and lead in it was found to be 1:1.008. In another experiment in which a 0.13 per cent. solution of pure sodium sulphide was titrated with lead nitrate the precipitate had exactly the same composition.

From these results it is clear that the sulphide is partly oxidised by oxygen present in the water or taken up during the titration, and that the quantity found, even with the smallest quantity of water, is less than that contained in the solid cyanide. I have attempted to estimate the necessary correction in three different ways.

(a) Solutions containing a known quantity of sulphide were made by adding measured quantities of a solution of sodium sulphide (containing the equivalent of 0.00568 gm. of potassium sulphide per c.c.) to solutions of 10 grms. of pure, sulphur-free sodium cyanide in 15 c.c. of ordinary tap water. Titration with a solution containing 6 grms. of lead nitrate per litre gave the following results:—

TABLE II.

Potass. sulphide added.	Potass. sulphide found.	Difference.
grms. 0.00284	grms. 0.0022	per cent. 23
0.00568	0.00454	20
0.00852	0.0068	20

The solution of sodium sulphide was, of course, tested just before using it, and the titrations with lead nitrate made as quickly as possible, that is in 3½ to 4 minutes.

The effect of making up all the solutions with water which had been well boiled and then cooled out of contact with air and which were only exposed to air during the titration was then tried.

III.

Two titrations of a solution of sodium sulphide (1.29 grms. per litre) gave 1.11 and 1.13 grms. The mean is 1.12 per cent. too low.

Three other tests in which 10 grms. of pure sodium cyanide were dissolved in 25 or 50 c.c. of this solution before titration gave 1.18 and 1.20 grms. (25 c.c.) and 1.13 grms. (50 c.c.). The mean is here 9.3 per cent. too low.

The reaction which takes place between sulphide and oxygen in presence of cyanide is $K_2S + KCN + H_2O + O = 2KOH + KSCN$ (compare Chief Inspector of Alkali Works, 42nd Report, 1905, p. 31), and therefore the 0.15 mgrm. of oxygen contained in 15 c.c. of water saturated with air at 15° can oxidise 1.05 mgrm. of potassium sulphide. The deficits of sulphide in the experiments of Table II. are 0.64, 1.14 and 1.7 mgrms. respectively, and, since the strong cyanide solutions used contain considerably less dissolved oxygen than an equal volume of water, it is evident that atmospheric oxygen must be taken up during the titration, and for this reason the error is not eliminated by the use of boiled solutions but merely diminished. This is seen to be the case in the experiments under III., which also show that the presence of cyanide hardly affects the amount of oxidation.

(b) The effect of the time required for the titration and of the quantity of water employed were studied more carefully, 1 c.c. of the lead nitrate solution used was equivalent to 1 mgr. K_2S .

In Table IV. the time which elapsed from adding the water to the cyanide to beginning the titration is given under "Dissolving"; 15 c.c. of tap water at 12° and 10 grms. of a sample of sodium cyanide were used in each case.

TABLE IV.

Dissolving (minutes).	Titration (minutes).	C.c. lead nitrate used.	Loss per minute.
2	3.5	1.03	0.0015
10	4	1.01	
63.5	3.5	0.93	0.00025
97.8	4	0.70	

In the next set the cyanide was first dissolved (10 grms. in 15 c.c.), some lead nitrate was then added, and the mixture allowed to stand for some time before finishing the titration.

TABLE V.

Dissolving (minutes).	Initial c.c. lead nitrate added.	Minutes in presence of lead.	Total c.c. lead nitrate used.	Loss per minute.
2	—	3.5	1.03	0.016
1.5	0.52	13	0.87	
2.5	0.52	24	0.70	0.015
2	0.52	48	0.61	0.0037
2.5	0.20	966	< 0.20	

In the last test no sulphide was left in the solution and the brown colour produced by the lead nitrate added had almost disappeared. It will be noticed that the initial rate of oxidation is increased about tenfold by the addition of lead nitrate.

A further set of tests was made to determine the effect of the quantity of water used, the time required for each operation being noted.

TABLE VI

C.c. of water.	Dissolving (minutes).	Titration (minutes).	C.c. lead nitrate used.	Loss per c.c. water.
15	2	4	0.9	0.91
15	1.5	4	0.92	
17.5	2	3	0.97	
17.5	1.5	4	0.96	0.97
25	2.5	4	0.87	
35	1.5	3.5	0.75	
50	2.5	2.5	< 0.55	0.012

In the last test the colour of the lead sulphide disappeared before the titration could be finished. That the test with 17.5 c.c. of water gives a higher result than those made with 15 c.c. is due to the latter quantity being insufficient to dissolve the cyanide at the low temperature used.

These results show that small variations in the time required to dissolve the sample do not appreciably affect the result; variations in the time of titration are more important, but, since the greater part of the lead solution can always be run in quickly, the time required is always approximately the same. The results of Table VI. show that, under the conditions of the test, 1 c.c. of water oxidises sulphide equivalent to 0.012 c.c. of the lead nitrate solution; if the quantity of water could have been reduced to zero, therefore, 1.18 c.c. of lead solution would have been used and the two first results are 23 per cent. and 18 per cent. too low respectively.

(c) An estimation of the sulphide in a sample of cyanide was made under conditions which exclude the possibility of oxidation. Twenty grms. of sodium cyanide were dissolved in a 0.2 per cent. solution of lead nitrate through which hydrogen had been passed until it was quite free from dissolved oxygen; the resulting precipitate of lead sulphide and basic lead cyanide was filtered off on a Gooch crucible and washed with the lead nitrate solution, the whole of the operations being carried out in an atmosphere of hydrogen. The precipitate was then oxidised and the sulphur in it weighed as barium sulphate. In this way the sample was found to contain sulphide equal to 0.046 per cent. of potassium sulphide. A direct titration made by dissolving 10 grms. of the cyanide in 15 c.c. of ordinary unboiled water and titrating as quickly as possible with lead nitrate (6 grms. per litre) gave 0.034 per cent. of potassium sulphide. The deficiency is here 26 per cent. of the sulphide actually present.

The three methods of ascertaining the error of the test agree, therefore, in showing it to be from 18 per cent. to 26 per cent. of the sulphide present when it is carried out in the following way:—10 grms. of the powdered cyanide are stirred quickly with 15 c.c. of ordinary water breaking up any lumps with a glass rod, any small undissolved residue usually goes into solution during the titration; the lead nitrate solution is then run in quickly so long as it produces a visible increase of colour, after this it is added gradually, the solution being tested by placing drops of it in contact with drops of the lead nitrate solution absorbed by thick blotting paper. The result is corrected by multiplying it by 1.25 or, more simply, by using a lead nitrate solution containing 2.4 grms. per litre and taking 1 c.c. of it as equivalent to 0.01 per cent. of potassium sulphide in the cyanide.

In this form a complete test can be made in about 10 minutes, and the results are accurate to 2 or 3 units in the third place of decimals, which is quite sufficient for all practical purposes.

Colorimetric methods.—In one modification of this method a solution of sodium plumbite, made by dissolving 60 grms. of lead acetate and 90 grms. of caustic soda in 1 litre of water, is added to the sulphide solution to be tested and the colour matched by adding a standard solution of lead nitrate to a solution containing an excess of sulphuretted hydrogen or of sodium sulphide, the two solutions being placed in cylinders of the same diameter filled to the same depth in the usual way. The assumption made is that when the depth of colour of the two solutions is the same they will contain the same quantity of lead sulphide. This is by no means the case. For

example, solutions containing sodium sulphide equivalent to 0.0006 gram. of potassium sulphide were treated with 2, 5, 10, and 20 c.c. of the alkaline lead solution and the colour matched by adding a solution of lead nitrate (0.15 gram. per litre) to a solution containing 0.015 gram. of sodium sulphide (total volume in each case=60 c.c.). The quantities of the lead nitrate solution required were 15.1, 11.8, 12.4, and 10.4 c.c. respectively. Again, solutions containing 10 grms. of potassium cyanide and 0.0015 gram. of potassium sulphide were treated with 50 c.c. and 5 c.c. of the alkaline lead solution and matched against a solution containing sulphuretted hydrogen equivalent to 0.425 gram. of potassium sulphide. The quantities of lead nitrate solution required were 15.1 c.c. in the one case, and 21.0 c.c. in the other. The quantity of sulphuretted hydrogen or of sodium sulphide used in the comparison solution also affects the result, for example, solutions containing 0.0006 gram. of potassium sulphide and 1 c.c. of the alkaline lead solution in 60 c.c. were matched against solutions containing 0.015, 0.03, and 0.075 gram. of sodium sulphide; 14.8, 12.4, and 10.9 c.c. of the lead nitrate solution were required in the three cases. The difference is not so large when different quantities of sulphuretted hydrogen are used, but it is in the same direction. Finally, the depth of colour is not the same in solutions of sodium sulphide and of sulphuretted hydrogen, two solutions containing sulphide equivalent to 0.033 gram. of potassium sulphide, were prepared: the one contained sulphuretted hydrogen, the other sodium sulphide; 10 c.c. of the lead nitrate solution added to the first gave the same depth of colour as 13 c.c. added to the second.

In all these experiments the solutions were made up just before use with water which had been boiled and cooled out of contact with air. It follows that the depth of colour of the lead sulphide is affected by the nature and quantity of the other constituents of the solution. Comparisons of colour are only possible so long as the lead sulphide remains colloidal. Linder and Pieton's work on colloidal arsenic sulphide (*J. Chem. Soc.*, 1895, 63, and 1905, 1914) suggests that the colloidal lead sulphide consists of complex molecular aggregates $n(\text{MPhS.H.S})$, in which the hydrogen is replaceable by metals. The colour would then depend on the values of n , m , and on the nature of the sulphide combined with the lead sulphide, which would, in their turn, depend on the nature of the substances present in the solution. Hence a reliable colorimetric estimation can only be made when the two solutions have the same composition. This condition is fulfilled in the ingenious method described by G. W. Williams (*J. Chem. Metall. and Min. Soc., S. Africa*, 1905, 6, 170; this *J.*, 1906, 137). Two equal quantities of the cyanide are dissolved in boiled water, the sulphide is removed from one of them by shaking with lead carbonate and filtering, the same quantity of alkaline lead solution is then added to each and the colour matched by adding a standard solution of sodium sulphide. Another advantage of the method is that atmospheric oxygen acts approximately equally on the two solutions, and therefore the error due to this source is eliminated to a great extent.

A sample of potassium cyanide tested by this method gave 0.0309 and 0.0296 per cent. of potassium sulphide, whereas the direct titration method described above gave 0.0246 and 0.0240 per cent. of potassium sulphide, or, after correction by multiplying by 1.25, 0.0307 and 0.0300 per cent. of potassium sulphide. The sample used in the experiments of Table VI. gave 0.013 per cent. of potassium sulphide by Williams' method, 0.012 per cent. of potassium sulphide by direct titration. The agreement is as good as could be desired.

A few experiments were made with the method described by W. Feld (this *J.*, 1903, 1068), in which the sulphide solution is distilled with excess of magnesium chloride in a current of carbon dioxide, the sulphuretted hydrogen evolved being absorbed in a known quantity of iodine solution acidified with hydrochloric acid. The apparatus used was that previously described (this *J.*, 1904, 244) with the addition of a set of potash bulbs containing iodine solution and a second I-tube containing a little $N/10$ sodium thiosulphate. In order to see whether any oxidation of sulphide takes place in the distillation,

a solution of sodium sulphide was (I.) precipitated with pure zinc chloride and the sulphur in the filtrate estimated, after oxidation, as barium sulphate. II. Another portion of the solution was run into a boiling solution of magnesium chloride and boiled until free from sulphuretted hydrogen, the residual sulphur being estimated as barium sulphate; (III.), a third portion was treated in the same way after adding a solution of 10 grms. of pure crystallised $\text{NaCN} \cdot 2\text{H}_2\text{O}$ in boiled water to it. The results were:—

Sodium sulphide used.	Residual sulphur calculated as sodium sulphide.		
	I.	II.	III.
grm.	grm.	grm.	grm.
0.162	0.0013	0.0024	0.0037
0.013	0.0005	0.0002	0.0001

It appears, therefore, that the sulphuretted hydrogen can be expelled quantitatively, and provided that a sufficiently long train of absorbing vessels is used it is easy to absorb it in the iodine solution. For example, in one test 0.0736 grm. of sodium sulphide was distilled and 0.0740 grm. found from the iodine used.

SUMMARY.

Of the three methods discussed the direct titration of sulphide by means of lead nitrate is the most rapid and simple; suitably corrected it is sufficiently accurate (for quantities of potassium sulphide under 0.1 per cent.). G. W. Williams' modification of the colorimetric method is more accurate, but it is slower, owing to the necessity of using boiled water and checking the strength of the standard sodium sulphide solution at frequent intervals. (A solution containing 2 grms. of potassium sulphide per litre, for example, lost 28 per cent. in 18 hours.) W. Feld's method is the most accurate, but it is far too slow for works' purposes, and it can only be used by a skilled operator.

I have pleasure in acknowledging Mr. Thomas Napier's skilful assistance in some of the analytical work. I am also indebted to the directors of the Cassel Cyanide Company, Ltd., for permission to publish the results.

Yorkshire Section.

Meeting held at Leeds on Monday, November 9, 1908.

MR. WALTER M. GARDNER IN THE CHAIR.

SOME CHEMICAL ASPECTS OF THE TEXTILE INDUSTRIES.

BY W. M. GARDNER.

Abstract of Chairman's Address.

In a great variety of manufactures the raw material is converted into the finished product by processes which in their essence are mechanical or chemical. More usually both mechanical and chemical operations are involved, and the two are frequently so intimately blended that the processes cannot be defined as either chemical or mechanical. For example, the manufacture of soap must be classed as a chemical industry, but the conversion of esparto grass into paper is chiefly based on mechanical treatment though involving some chemical processes, while the mechanical engineer is concerned almost exclusively with mechanical operations, though in many directions he is bound to make incidental incursions into chemical science.

The manufacture of a textile fabric is another case in which both chemical and mechanical operations are usually involved, though what may be termed the fundamental operations are mechanical. In the carding or combing and spinning processes the raw fibrous material is transformed into a coherent thread and by subsequent more

or less complex interlacings of individual threads, the woven fabric is produced. Since natural fibrous raw materials are available, a piece of cloth may thus be produced without the intervention of any chemical process whatever, and in attempting to show the great field which exists for industrial chemistry in connection with textile manufactures, one cannot be charged with selecting an industry to which chemical manipulation is fundamental.

I have selected the textile trade partly for this reason, but mainly because it is the one of which I have the most intimate chemical knowledge, and my object is to make some contribution to the discussion of the most interesting points which have been very prominently raised in recent addresses.

Much has been heard during the last few years about the decadent condition of the British chemical industries, and it has to be admitted that many notable examples can be adduced in which chemical trades, originated in this country, have been almost entirely lost to us. This has been frequently dealt with, and its causes analysed by those much more competent than I am, and my only reason for again mentioning a fact which we all deplore is to express the opinion that undue prominence given to our failures is very apt to depreciate the value of the great amount of energetic and successful work which has been and is being done in other directions.

In discussing this matter it is obviously necessary to define what is meant by the chemical industries, and this may be conveniently done by a reference to the subjects dealt with in our JOURNAL, and I claim that much misrepresentation has arisen from want of care in using this term. Surely "the shadow of the cypress" does not rest on the whole of the great industries officially recognised by this Society as chemical industries, and even as regards the minor industry (from the chemical point of view) of textile manufacture, it is easy to show that an enormous expansion of the chemical side has taken place in recent years and that an ever increasing number of well-trained chemists is in demand.

In his most interesting and valuable Presidential Address to the Chemical Society in 1907, Prof. Meldola made an eloquent and well reasoned appeal for increased facilities to be provided for the carrying out of research work in chemistry at the many Technical Colleges and Polytechnics which are provided with well-equipped laboratories. Speaking as he was to the representatives of pure chemistry, Prof. Meldola obviously had in view chemical research as distinct from technical research, and he emphasises the necessity of a training in research and the development of the research spirit which is all important in the working out of new processes.

In regard to many branches of the textile industries it is very satisfactory to be able to say that in several of the larger Technical Colleges much work in the nature of technical research is carried out by the advanced students and is often followed up by investigation for improving or cheapening processes when the students obtain positions in works. In this way both staff and students are being kept in intimate contact with the industries concerned.

In connection with this question of research work it may be interesting to record that at any rate some of the local education authorities who are now mainly responsible for the Technical Colleges, are realising the responsibility resting upon these Institutions to add their quota to the sum of knowledge; and in the Institution over which I have the honour to preside (the Bradford Technical College) a highly qualified lecturer has recently been appointed specifically to devote his time to chemical research.

Turning now to a short review of the chemical industry of textile manufactures, it may be fairly claimed that the chemist has made some remarkable contribution both as regards the actual provision of raw materials, the production of new decorative effects, and in imparting new and valuable properties to fabrics.

In the matter of raw material one textile fibre, artificial silk, is of purely chemical origin. It is invariably made from cellulose as a raw material, this being brought into solution in various ways and subsequently regenerated in the form of fine filaments. Chardonnnet's original

process (1889) was to convert cellulose into the tri- and tetra-nitrate, which was dissolved in alcohol-ether; the solution was then forced through very fine orifices into a heated chamber, which volatilised the solvent. The filaments were then "denitrated" in various ways.

The great defects of artificial silk as a textile raw material have been its low strength, its poor covering power, and the difficulty found in its manipulation, but these defects have now been largely eliminated.

The chemist has also enriched the textile industries by the production of what is practically a second new fibre by the invention of the "lustreing" of cotton by mercerisation. This process, which imparts to cotton very much the appearance of silk, was initiated and developed in this country. The dyeing properties of the mercerised cotton also differ materially from those of ordinary cotton.

Other chemical treatments of the various textile fibres are employed for producing special effects or special properties. For example, by different treatments the dyeing properties of fibres may be entirely altered. In response to the offer of a prize of £10, Messrs. C. F. Cross and Briggs submitted a process by which cotton may be made to resist (that is, will not dye with) direct colours such as the benzidine dyes. The process consists in treating the cotton with acetic anhydride, acetyl chloride, and zinc chloride, and the acetylated cellulose has quite peculiar and valuable properties in several directions. The discovery of this process has no doubt been of considerable service to the patentees as well as to the trade generally, and this example may serve to illustrate the nature and value of chemical research of a technical nature as applied to the textile industries and incidentally the value of bringing the trade problems to the notice of chemists by means of journal publication.

Other directions in which chemical treatment of fibres has been of great value are the production of unshrinkable wool fabrics and unflammable cotton materials, both of which have been the subject of a great amount of technical research before success was attained.

Wool washing is the process of removing from wool fibre the natural grease with which it is encrusted. This is done by emulsifying the grease by means of a solution of soap and alkaline carbonate. The process gives rise to very large volumes of waste liquors which contain much free and combined fat. If these liquors are run into the sewers in considerable quantity they greatly complicate the work of the sewage engineer, as in fact is the case in Bradford, where about £12,000 per annum

is expended for sulphuric acid with which to separate the fatty matter from the sewage.

The recovered fat has a value of about £5 10s. to £6 per ton and about 40 tons per week is recovered from the Bradford sewage. In the larger wool-washing works, the suds are treated before running to waste, and the grease converted into soap, lubricating oil, and lanolin. In one works in Bradford (not the largest) as much as 50 tons of grease per month is recovered, its value being £9 to £10 per ton. This is a particular case of the large chemical question of the treatment of effluents, in which direction much investigation is proceeding and which is one of the important features of the work of a chemist in textile works.

Leaving aside the chemical work involved in such processes in textile manufacture as bleaching, dyeing, printing, etc., which is too extensive a subject to be touched upon, reference may finally be made to one most important branch of the work of a chemist in any textile works, viz., the investigation of defects which may arise at any stage of manufacture.

The work involved in such investigations is often of great interest and of very wide scope. It frequently happens that any solution of the difficulty is impossible in the absence of an acquaintance with the whole range of operations—mechanical as well as chemical—through which the material has passed. It is in fact research work of no mean order and the carrying out of such work by advanced students is the most valuable kind of training. From its very nature much of the work is unsuitable for publication and commercial considerations usually prohibit publication in any case. It appears to me, however, that in carrying out technical research of this character, works chemists and Technical Colleges are fulfilling their truest function. In the case of teaching institutions it provides for the all important necessity of keeping in close touch with the industries they serve.

If it were possible to give publicity to investigations of this character, I feel sure that criticisms of the small amount of original work carried out in Technical Colleges would not be so severe.

I have attempted to show that even in apparently remote directions, such as the textile trade, there is a wide scope for chemical research and abundant opportunity for the employment of well trained (if specially trained, chemists. Chemistry is permeating the textile industry and the outlook for the future of this great industry is very hopeful, even from the chemical student's point of view.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows.—

English.—8s. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25c. each, to Bellin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars), to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Dryer: A mechanical rotary or revolving — for removing and expelling moisture from megass, sawdust, sand, and particles of various substances. L. Jones, London. Eng. Pat. 25,131, Nov. 13, 1907.

A DRUM, *a*, provided with vanes, *b*, forming compartments, *l*, is rotated in a flue, *a*, through which the heating medium is transmitted. By means of a damper, *h*, the volume of heating medium passing round the drum may be regulated. The material to be dried is fed through an opening in the end of the drum on to a distributor-plate, *i*, which can be rotated about the axis, *j*, by the external lever, *k*. When charging, the distributor is fixed in the inclined position shown, and the material falls into the compartments, *l*, as they pass below its lower edge. When half the compartments are charged the feeding is stopped, and the rotation continued. As each compartment attains

the highest position, its contents are dropped on to the distributor, *i*, and are conducted into the compartment

opposite. When the drying is complete, the distributor, *i*, is turned into the horizontal position and the contents of the compartments are successively dropped on to the plate, *i*, from which they are removed; the plate, *i*, is then turned into a sloping position again and the drum is recharged without stopping its rotation.—W. H. C.

Filtering machines. G. Ridgway, Kalgoorlie, W. Australia. Eng. Pat. 5830, March 16, 1908.

The claim is for improvements in the filter described in Eng. Pat. 11,623 of 1906 (this J., 1906, 989). A number of groups of filter-frames, formed of perforated pipes bent into a U-shaped frame, which is covered with filter-cloth and kept distended by coir matting placed in the interior, are supported by chains from a circular framework, which is rotated on rollers and rails above an annular tank. The latter is divided into four compartments which serve respectively for the pulp to be filtered, the washing liquid, and as a drying and a discharge chamber. The ends of the U-shaped pipes of each group of filters are connected by flexible tubes to the radial arms of a central hollow shaft or chamber, so that the frames are successively connected automatically to a vacuum pump and to a supply of compressed air. The frames pass slowly through the pulp which is kept agitated in the trough, and the liquid is sucked through by the vacuum, leaving the solids as a cake on the surface of the filter-cloth. As the groups of frames approach the partitions, they are lifted over them by an arrangement of quadrants and rollers and again lowered into the next compartment. After washing and drying, the vacuum is automatically cut off, and compressed air is admitted into the interior of the frames as they pass through the discharge compartment. At the same time a supply of water from the central shaft is admitted to a chamber at the top of each frame and flows down the surface of the cloth on each side, and the latter is also sprayed with water on both sides from a number of jets; this causes the cake of solid matter to peel off, and the frames are ready to pass into the pulp collecting again.—W. H. C.

Pressure-filter. C. W. Merrill, Lead, S.D. U.S. Pat. 905,341, Dec. 1, 1908.

The claim is for a filter-press provided with direct inlet and outlet pipes to the chambers, so arranged that when the outlet pipe is open, a supply of cleansing medium is introduced into the chambers under pressure, to drive out the solid matter.—W. H. C.

Pumps; Centrifugal —. Allgem. Elektrizitäts-Ges., Berlin. Eng. Pat. 21,470, Oct 10, 1908. Under Int. Conv., Jan. 30, 1908. Addition to Eng. Pat. 14,439 of 1907, dated June 25, 1906.

In order to increase the pressure on the entrained fluid and at the same time to diminish the friction on the entraining fluid, the channels in the stationary conducting ring are constructed with converging walls for a portion of their length and with parallel walls for the remainder of their length. In order to entrap more of the entrained fluid, the passages are combined in pairs so as to have a common inlet.—W. H. C.

Crystalline substances; Method of recovering — from liquor and drying the same. E. Ordway, New York. U.S. Pat. 905,568, Dec. 1, 1908.

The liquor is concentrated in a vacuum evaporator and is circulated along with the separated crystals through a closed collecting tank. The crystals are retained in the tank by a perforated plate or shelf, and the liquor returns to the evaporator. When the collecting tank is sufficiently filled with crystals, the inflow of liquor is stopped and the liquor in the tank is drained back into the evaporator. Connection with the evaporator is then closed and the crystals are dried in the collecting tank, before removal, by passing a current of heated drying medium through the tank.—W. H. C.

Evaporators; Continuous single or multiple effect —. E. Jolicard. Fr. Pat. 392,616, Sept. 30, 1907.

The evaporating tubes may be vertical or inclined, and rotating metallic brushes, scrapers, or flexible plates, are provided inside the tubes for stirring the liquid to be treated, or the powder produced. The application of such evaporators or parts thereof, is claimed for the pasteurisation or sterilisation, heating, cooling, concentration, and desiccation of liquids.—C. J. G.

Still. E. Flick. Fr. Pat. 392,674, July 18, 1908.

The plates, *D*₁, of the column surmounting the still are provided with holes, each of which has a suitably shaped cover, *D*₄, and a steam inlet, *D*₃. The liquid trickles over the outside of *D*₄, as shown by the arrows, the ascending steam being thus forced through the ring of liquid between *D*₃ and *D*₁. The application of the apparatus to the manufacture of formic acid is described.

II.—FUEL, GAS, AND LIGHT.

Coals; Philippine —. A. J. Cox. Eng. and Min. J., 1908, 86, 1058–1059.

RESULTS are given of the investigations made by the Bureau of Science, Manila, on the quality of Philippine coals. The coals occur abundantly on Batan Island, Cebu, Polillo, and elsewhere, and show a remarkable uniformity throughout. They resemble in appearance a bituminous coal, but have a rather lower calorific value, are entirely non-caking, and form no clinker. They contain from 35 to 46 per cent. of volatile combustible matter and 2.5 to 6 per cent. of ash. They are a little inferior to the Australian and Japanese coals at present imported, but will be able to compete successfully with them when the cost of inland transport has been reduced. The author considers that the coals obtained from nearer the surface are chiefly suitable for use in gas producers, and the deeper deposits for steam raising, though, owing to their non-caking properties, it may be advisable to mix a small proportion of a caking coal with them. Tables of analyses, etc., are given.—F. R.

Anthracite producer practice; Notes on —, G. S. Stone, J. Industrial and Eng. Chem., 1909, 1, 11-13.

NOTES of experiments, made under working conditions of an anthracite producer gas-plant connected with a spelter furnace, are given. The useful effect of producer gas is shown to depend on the steam supplied to the producer, the thermal capacity of the gas, and the composition and thermal capacity of the waste gases at the furnace temperature, as well as on the calorific power of the gas. It was found that the useful effect in the spelter furnace varied almost directly as the percentage of carbon monoxide in the producer-gas and not as the calorific power of the gas nor as the net heating power under furnace conditions. A table is given with the analyses of the gases, and the heat balance of the furnace, for each experiment. —J. H. J.

Safety explosives; Tests with —, Beyling, See XXII.

PATENTS.

Fuel, artificial; Treatment of coal for the production of —, F. V. Hadlow, Buxted, Eng. Pat. 3189, Feb. 13, 1908.

ARTIFICIAL fuel is produced by mixing coal in a pulverised condition with an alkali silicate solution and a solution produced by adding lime to an aqueous solution of sugar, and water in sufficient proportion to ensure that the product shall be hard, waterproof, and free from smoke and dust when burned. —E. C.

Briquetting carbonaceous materials; Method of —, W. T. Griffin, Limoges, France; J. E. Blake, I. S. Graves, and C. H. Clarke, executors of W. T. Griffin, U.S. Pat. 905, 693, Dec. 1, 1908.

THE carbonaceous materials are first heated until the water and lighter hydrocarbons are driven off and the material has assumed a semi-plastic condition, but is not coked. It is then slightly cooled and compressed into briquettes. If two different kinds of material are used, one of which contains a larger proportion of bituminous matter than the other, they are separately heated to different temperatures and when one of them is in the semi-plastic condition, they are mixed together and briquetted. —W. H. C.

Fuel, artificial; Manufacture of —, The Calor Co., Ltd, Fr. Pat. 393,218, Aug. 11, 1908, Under Int. Conv., Feb. 6, 1908.

BRIQUETTES are prepared from powdered coal, lignite, etc., with the aid of chlorinated liquid hydrocarbons as binding agent. The binding agent is prepared by treating suitable liquid hydrocarbons, e.g., coal tar, with bleaching powder, with or without subsequent addition of lime, or with sulphur chloride or chlorine gas, with subsequent addition of lime. —A. S.

Alcohol; Dehydrated, for use in motor-cars and boats and other internal combustion engines and for lighting and heating, J. Novel, First Addition, dated July 25, 1908, to Fr. Pat. 380,310, July 27, 1907 (this J., 1908, 14).

ALCOHOL is distilled in presence of acid (e.g., 20 per cent. of sulphuric acid), to which may be added ether or acetone as carburising agents. —F. C.

Gas; Manufacture of — from tar, oil, and similar substances, F. G. L. Rincker and L. Wolter, Fr. Pat. 393,114, July 28, 1908.

THE essential feature of the invention, is the introduction of steam into the gas generator, after the introduction of the combustible materials on to a bed of glowing fuel therein, whereby the proportion of nitrogen in the gas is diminished and a richer gas, containing hydrogen, is obtained. The fuel (tar, oil, etc.) and steam are introduced at the upper end, and the gas is withdrawn from the lower end of the generator. —F. C.

Gases; Purifying and cooling hot —, Soc. Anon. des Hauts Fourneaux, Forges et Aciéries de Pompey, Fr. Pat. 392,758, Oct. 5, 1907.

HOT gases, especially those from blast-furnaces, are passed through an apparatus consisting of a number of vertical tubes, enclosed by concentric jackets. The gases pass through the jackets and outside the tubes, through which air is continuously passing in a direction opposite to that of the gases. Entrained moisture is thus condensed, and this in turn assists in the deposition of dust suspended in the gases. —C. J. G.

Incandescent gas mantles; Manufacture of —, J. T. Robin, Streatham, from S. Salomon, Hamburg, Germany, Eng. Pat. 25,657, Nov. 19, 1907.

THE collodionised mantle is dipped in a solution similar to the impregnating solution used in the earlier stages of its manufacture, for example, a 25 to 50 per cent. solution of thorium nitrate containing a small percentage of cerium nitrate. When the mantle so treated is burnt off, the nitrates in the coating are converted into oxides; the coating mends any fractures which may have been formed during handling or transport. —A. T. L.

Arc lamp electrode, H. S. Hatfield and F. M. Lewis, Brighton, England, U.S. Pat. 904,532, Nov. 24, 1908.

AN electrode for enclosed arc lamps is composed of carbon, calcium fluoride, and carborundum. The addition of the fluoride and carborundum improves the steadiness of the light. The relative proportions of the calcium fluoride and carborundum are as 8:5. —A. T. L.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Benzine [petroleum spirit]; Commercial —. M. Rakusin, Caoutchouc et Gutta-Percha. 1908. 5. 2504—2512.

THE author describes briefly the manufacture, properties, applications, and methods of storing and transporting commercial benzine.

Viscosity numbers (Engler) and flashing and burning points in oil mixtures; A comparison of the calculated and determined —. H. C. Sherman, T. T. Gray, and H. A. Hammerschlag. J. Industrial and Eng. Chem., 1909, 1, 13—17.

It was found that in mixtures of two petroleum lubricating oils, or of one petroleum oil with a fatty or sperm oil, the Engler viscosity numbers and the flashing and burning points were always lower than those calculated from the percentages of the constituents, assuming those properties to be additive like the specific gravity. The difference between the calculated and observed results, increased with the difference in properties of the two constituents. In some cases the difference between the two results was greatest in the case of the mixture containing equal amounts of the two constituents, but in general the difference was greatest when the mixture contained the least amounts of the lighter or low-test oil.—J. H. J.

Methyl alcohol; Dehydration of commercial —. J. Gyr. See XX.

PATENTS.

Tar; Distillation of —. T. Wilton, Beckton, and G. Wilton, London. Eng. Pat. 26,910, Dec. 5, 1907.

TAR is freed from water, before distillation in pot stills, by heating to about 130° C. under a pressure of 30 lb. per sq. in., and then reducing the pressure so that the water is liberated as steam without liberating the main volatile constituents of the tar. The process is carried out by forcing the tar through a heated coil, from which it is delivered in a thin stream into a chamber at a lower pressure. The steam and vapour are condensed to recover the light oils, and the tar is fed into the stills.

—A. T. L.

Peat; Combustion of — for the manufacture of ammonium sulphate. E. Dromain. Fr. Pat. 392,979, Oct. 12, 1907.

FLUES, such as simple trenches covered with iron plates, are constructed in the peat-bog itself or its immediate vicinity, and in these the peat is burned. The flues extend to the ammonia-recovery plant, and artificial draught may be necessary if the distance be great; they are packed with "dry" peat overlaid by wet peat. —F. SOON.

Rust-preventing and lubricating agent [from mineral oils]; Preparation of a —. F. W. Klever, Ger. Pat. 204,906, April 4, 1906. Addition to Ger. Pat. 174,906 (see Eng. Pat. 27,254 of 1905; this J., 1907, 86.)

By means of the alkali salts of the fatty acids of castor, hemp, palm, rape, cottonseed, sesame, or olive oils or of resin acids, and alcohols of high boiling point, emulsions can be prepared from petroleum illuminating oils or any other mineral oils of higher density, by the process described in the main patent.—A. S.

Petroleum and other liquids capable of volatilisation; Rectification and fractional separation of crude —. E. Guillaume, Paris. Eng. Pat. 15,267, July 18, 1908. SEE Fr. Pat. 390,119 of 1907; this J., 1908, 1013.—T. F. B.

Powders, tablets, etc., completely soluble in water; Preparation of — containing substances originally insoluble. Fr. Pat. 392,478. See XX.

IV.—COLOURING MATTERS AND DYESTUFFS.

PATENTS.

Halogen indigo derivatives; Manufacture of —. O. Imray, London. From Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst a/Main, Germany. Eng. Pats. 25,513, Nov. 18, 1907, and 26,276, Nov. 27, 1907.

By treating dihalogen-indigos with an excess of bromine in the cold or whilst gently heating, greenish-black, highly brominated products are formed, which, when treated with hydrogen bromide or agents capable of eliminating bromine, become blue, yielding dyestuffs which dye greener and clearer shades than the parent dyestuffs. Example: If dibromo-indigo be stirred with 4 times its weight of bromine, a greenish-black product is formed. On heating 10 parts of this product with 10 parts of sodium hydrosulphite of 80 per cent. strength while suspended in water to which sodium carbonate or ammonia has been added, a grey-greenish leuco-product is formed which may be filtered and stirred with water or molasses to form a commercial paste.—P. F. C.

Brominated, halogenised indigos; Manufacture of highly —. O. Imray, London. From Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst a/Main, Germany. Eng. Pats. 25,514, Nov. 18, 1907, and 26,275, Nov. 27, 1907.

By stirring dibromo-indigo with concentrated sulphuric acid, whereby the sulphate of dibromo-indigo is formed, and then treating the mixture with an excess of bromine at the ordinary temperature or while gently heating, products are obtained, which, on pouring into an ice bisulphite solution become blue and yield highly brominated indigo. The resulting dyestuff dissolves in concentrated sulphuric acid with a blue colour and dyes in the vat a clearer and greener blue than that obtained with dibromo-indigo. A similar product is obtained by using a dichloro-indigo or a chlorobromo-indigo as the starting point. Example: One part of dibromo-indigo is slowly introduced, with stirring, into 4 parts of concentrated sulphuric acid of 66 B. After standing for some time, 1.5 parts of bromine are added to the cooled and well stirred mixture. The temperature is next raised to about 45° C. for some hours. Stirring is continued for a time at the ordinary temperature and the whole mixture is then poured on to a mixture of ice and bisulphite, filtered, and washed. These highly brominated products may also be made directly from indigo by stirring it at as low a temperature as possible with concentrated sulphuric acid of about 85—99 per cent. and then brominating with an excess of bromine, first in the cold and finally while gently heating.—P. F. C.

Pentabromo-indigo; Manufacture of —. Farbwerke vorm. Meister, Lucius, and Brüning. Fr. Pat. 392,638, June 29, 1908.

PENTABROMO-INDIGO can be prepared by heating indigo or one of its bromine derivatives with an excess of bromine, preferably in the presence of a halogen carrier and with or without the addition of sulphuric acid. Example 1: 21 parts of dibromo-indigo are added to 180 parts of bromine in which 1–2 parts of iodine are dissolved, the temperature being kept low during the mixing. The mixture is then heated for some hours at 80° C. under pressure. The excess of bromine is next removed and the product is heated with a solution of sodium bisulphite, filtered, and washed with warm water. Example 2: 42 parts of dibromo-indigo are stirred with 252 parts of sulphuric acid of 66 B. 150 parts of bromine, in which 2 parts of iodine are dissolved, are then added to the well-cooled mixture and the whole is heated to a temperature of 70–80° C. for some hours in an apparatus provided with a reflux condenser. The excess of bromine is next removed and the residue is poured on to a mixture of ice and bisulphite, filtered and washed. The pentabromo-

indigo obtained by these methods dyes shades which are greener than those obtained with the parent dyestuff, especially when viewed in artificial light.—P. F. C.

Indigo White; Process of transforming — and its substituted products into bromo-derivatives containing bromine which is readily eliminated, and manufacture of bromine substitution products from these derivatives. Farb. vorm. Meister, Lucius, and Brüning, Fr. Pat. 393,279, Aug. 13, 1908. Under Int. Conv., Aug. 30, 1907.

WHEN Indigo White or its mono- or di-halogen or dimethyl substitution derivatives are treated with bromine in the presence or absence of a solvent and the mixture heated, greenish-black compounds are obtained containing a large amount of bromine, of which a part can readily be eliminated by heating the substances in a current of air, or in a suitable liquid, or by treatment with bisulphites, etc. In this way dyestuffs are produced with a high content of bromine and dyeing cotton in the vat in clear blue shades. Example 1: 100 parts of bromine are added to a mixture of 26 parts of Indigo White and a small quantity of carbon tetrachloride, and the whole is then digested for some time at 60–120° C., preferably under a slight pressure. A catalyst such as iodine may also be added. The product is freed from excess of bromine by adding carbon tetrachloride and is immediately converted into the new dyestuff by boiling this mixture with sodium bisulphite equal to ten times the weight of the black intermediate product. The dyestuff gives greenish-blue shades on cotton. Example 2: Dibromo-indigo White is treated in the same way and yields a dyestuff similar to that produced from the unsubstituted compound.—J. C. C.

Indigo compounds; Manufacture of new — P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 4123, Feb. 27, 1908.

New tri- and tetra-bromo-derivatives of Indigo are obtained by treating Indigo or chloro-derivatives of Indigo with bromine in the presence of concentrated sulphuric acid. The new dyestuffs are greener and more soluble in organic solvents than those described in Eng. Pats. 5122 and 10,326 of 1907 (this J., 1908, 71 and 156). Example: 10 parts of finely powdered Indigo are mixed with 250 parts of well cooled concentrated sulphuric acid, 20 parts of bromine are gradually added, and after two hours the mixture is slowly heated to 40° C. and kept at that temperature for 12 hours. On pouring into water, tetrabromindigo separates. For the preparation of tribromindigo, 14 parts of bromine are used, the mixture being heated to 30° C. for 3 hours. The shades produced by both derivatives are similar, but the dyeings from tribromindigo turn white with concentrated nitric acid, whilst those from tetrabromindigo resist the action of the acid fairly well.—J. C. C.

Galloyanines; Manufacture of condensation products of — with ammonia. Farbwerke vorm. L. DuRand, Huguenin, und Co., Hünningen, Germany. Eng. Pat. 12,067, June 3, 1908. Under Int. Conv., June 3, 1907. Addition to Eng. Pat. 15,138 of 1907 (see Fr. Pat. 378,923; this J., 1907, 1194).

CONDENSATION products of galloyanines with ammonia are obtained by heating a galloyanine derived from gallanic acid with ammonia in the presence of an aromatic nitrohydrocarbon. Example: A mixture of 60 litres of alcohol, 30 kilos. of a galloyanine derived from gallanic acid, such as the condensation product from nitrosodiethylamine and gallanic acid, and 5 kilos. of dinitrobenzene are heated with 100 litres of an alcoholic solution of ammonia containing 15 kilos. of ammonia in an autoclave to 110–130° C., until a sample dissolves in sulphuric acid to a brown solution. The excess of ammonia and part of the alcohol are distilled off, the mass cooled, filtered, washed with alcohol, and dried. The product is best applied in the form of its leuco-derivative. The dyestuffs obtained in this way dye chrome-mordanted wool in greenish-blue tints.—J. C. C.

Triaminobenzene derivatives and dyestuffs of the Safranine series; Production of —. Badische Anilin und Soda Fabrik. Fr. Pat. 392,890, Aug. 11, 1908. Under Int. Conv., Dec. 19, 1907, and Jan. 1, 1908.

DERIVATIVES of 1:2:4-triaminobenzene-5-sulphonic acid of the type, $\text{SO}_3\text{H}\cdot\text{C}_6\text{H}_2(\text{NR}_1)_2(\text{NR}_2\text{R}_3)$ (R_1 = a simple or substituted acyl, alkyl, or aryl radical, R_2 and R_3 = hydrogen atoms or simple or substituted identical or different, acyl, alkyl, or aryl radicals) by treating 1-nitro-2:4-dichlorobenzene-5-sulphonic acid with the corresponding amines and reducing the nitro-group. The two chlorine atoms can be replaced by different amines because the atom in the ortho position to the nitro-group is first attacked and the other chlorine atom is only removed by prolonging the action or employing a higher temperature. By condensing these acids with a simple or substituted aromatic monoamine (with a free para-position), indamines are formed which on oxidation furnish the corresponding safranines, and if the acids are heated with $\beta\beta$ -hydroxynaphthoquinoneimines of the type, $\text{O}:\text{C}_{10}\text{H}_5(\text{OH})\text{NR}_1$, corresponding naphthosafranines are produced. The dyestuffs obtained in this way vary from red to greenish-blue and are suitable for dyeing wool and silk. Examples are given describing the preparation and condensation of 1-amino-2:4-dianilinobenzene-5-sulphonic acid with ethylbenzylanilinesulphonic acid, phenyl-1:6- (or 1:7) naphthylaminesulphonic acid, 2-hydroxy-1:4-naphthoquinoneanil-4', -6- and 8-sulphonic acids, and 2-hydroxy-1:4-naphthoquinone-4'-aminoanil-3'-sulphonic acid, of 1-amino-2-sulphamino-4-*p*-acetylaminonaphthobenzene-5-sulphonic acid with ethylbenzylanilinesulphonic acid and diethylmetanilic acid, of 1:4-diamino-2-anilinobenzene-5-sulphonic acid with ethylbenzylanilinesulphonic acid and 2-hydroxy-1:4-naphthoquinoneanil-4'-sulphonic acid, and of 1-amino-2-sulphamino-4-anilinobenzene-5-sulphonic acid with diethylmetanilic acid.—J. C. C.

Monoazo-dyestuff; Manufacture of a — capable of being applied as a bluish-red pigment. K. Merz, Fr. Pat. 392,914, Aug. 3, 1908; Under Int. Conv., Aug. 3, 1907.

THE monoazo-dyestuff prepared by combining diazotised 2-naphthylamine-8-sulphonic acid with 2-naphthol-3-carboxylic acid in alkaline solution gives, when transformed into the barium or calcium salt, a bluish-red or Bordeaux pigment respectively, which is very fast to light and possesses good covering power.—J. C. C.

Colouring matters of the anthracene series; Manufacture of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 27,187, Dec. 9, 1907.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES YARNS, AND FIBRES.

Artificial silk industry; Progress of the — W. P. Dreaper and J. G. Davis. J. Soc. Dyers and Col., 1908, 24, 294—297.

THE world's output of artificial silk is now about 5,000 tons per annum. In 1906 it was 8 tons per day as against 14 tons per day at present. Two new companies have been registered in this country to produce artificial silk, "Thiele" and "Glanzstoff" artificial silks respectively. The English output is estimated at 270 tons per annum. Both the Thiele and Glanzstoff processes dispense with the use of gun cotton and its solvents. It appears that the profits on the manufacture of nitrocellulose-silk have decreased, whilst those of companies working other processes have mostly increased, and in spite of its brilliance the gun cotton product is apparently being slowly displaced by those prepared directly from cotton. There is nothing to show that the acetocellulose product has been brought within the range of commercial production. It appears to have the defect that the fibre tends to crystallise, with consequent breaking of the filament. The viscose factory at Coventry has made substantial progress and the use of the product is increasing. It is supplied in sizes of 120 deniers and upwards; as now manufactured it does not become yellow on keeping, and an extended output is contemplated. There will probably be a steady growth of the industry during the next few years, and the production of yarns down to 30 deniers by the "Thiele" process will be commercially possible. During the past year the defects of decreased strength and elasticity on wetting have been favourably modified, whilst the brightness of the product is as great as previously. The individual fibres of boiled-off Thiele silk of 22 deniers are as fine as those of the natural product.

—E. F.

Chroming of wool. C. Gavard. Färber-Zeit., 1908, 19, 345—357.

COMPARATIVE experiments with ten different chrome dyestuffs showed that good results are obtained by using much smaller proportions of bichromate for mordanting or for after-chroming than are recommended in the recipes supplied by the makers of the dyestuffs. In general it is advantageous to use formic acid in place of tartar in mordanting, and also to add formic acid to the bichromate solution used for after-chroming. The detailed results of the author are given in a series of tables.—A. S.

Dyeing and cleaning [textile fabrics]; Recent improvements in — F. J. Farrell. J. Soc. Dyers and Col., 1908, 24, 289—294.

THE process of dry cleaning consists in treating the articles to be cleaned with benzine or solvent naphtha, with the addition of "benzine soaps," in a cylindrical washing machine. "Benzine soaps" are almost anhydrous metallic oleates. The articles are then rinsed in benzine or solvent naphtha free from soap, centrifuged, and dried in a steam-heated chamber. In order to avoid loss of the volatile solvent and danger of fire, many devices have been proposed for conducting all these operations in a closed circuit, but this has only been done with success during the last few years. Fire risks in dry cleaning establishments have greatly decreased owing to

the adoption of precautions, among which are:—The general use of soluble oleates except in the final rinsings; these convert the benzine into an electrical conductor and so prevent sparks due to friction; the earthing of all machines, the employment of appliances to prevent flames from passing down pipes to the storage tanks, the fitting of readily fusible units in the chains holding the counter-balance weights of machine lids, so rendering the latter self-shutting in case of fire, and the use of asbestos blankets to extinguish small fires. The use of closed circuits is better for employees, as the toxic effects of benzine vapour are thus avoided. In the wet cleaning process, amylolytic enzymes have largely come into use for removing the old dressing from fabrics. These extracts, of which "Diasol" is a typical preparation, convert the starch into sugar and also have a distinct solvent action on other impurities, so that much less soap is required than would otherwise be the case. Many of the soluble starches now on the market avoid the necessity of starching twice to obtain the required degree of stiffness for very stiff goods. In modern methods of preparing soluble starch a minimum of acid (sulphuric is said to be best) is used, and is not removed, though it may be neutralised by the addition of borax, alkali acetate, or alkali. The electrolytic production of hypochlorite on the small scale from salt solutions is now practically utilised. The cost of available chlorine need not exceed one-third of a penny per gallon of liquor containing 3 grms. of available chlorine per litre. Sodium perborate has also been recently introduced, and may supersede hydrogen peroxide, which is expensive and unstable. The perborate is used as a bleaching agent in the same way as hydrogen peroxide. The stable hydrosulphites are useful in wet cleaning, especially for flannels. Titanous chloride is useful in clearing coloured goods (e.g., fabrics with coloured embroidery) in which the colour has bled into the white. A superfatted sulphonated castor oil soap ("Tetrapol"), mixed with carbon tetrachloride, is said to have a high efficiency as a solvent of grease and does not affect the most delicate colours. It does not form insoluble calcium soaps, and can therefore be used with hard water. In dyeing, the increase in the range of direct cotton colours yielding uniform shades on cotton, wool and silk, has proved of much service, as have also the many improved methods of stripping, such as the use of stable hydrosulphites. Nitric acid and chromic acid, which were formerly used for stripping woollen goods, left a yellow or yellowish-brown ground. By the use of hydrosulphites, a pale ground is obtained on which almost any shade can be dyed. Stiffening agents are often necessary, which will give the required finish to the lining and at the same time will not affect the colour of the face fabric. Starch shows up on wool; and gelatin, though in some cases the only satisfactory dressing, is expensive, and may often be replaced by "Feculose," which is an acetylated starch product. Formic acid is of use in garment-dyeing owing to the increased penetration obtained with it. It is now as cheap as the less satisfactory acetic acid.—E. F.

Alkali-cellulose; Constitution of — O. Miller. See XIX.

PATENTS.

Soda-lye; Process and apparatus for removing — by means of steam from fabrics saturated with said lye for purposes of mercerisation. O. Venter, Chemnitz, Germany. Eng. Pat. 202, Jan. 3, 1908. Addition to Eng. Pat. 45,352 of 1907 (this J., 1907, 1275).

THE fabric is sprinkled with a dilute soda-lye coming from that compartment of the washing machine which contains the strongest washings, and is subsequently exposed to the action of steam as described in the main patent.

—P. F. C.

Dyeing fabrics in the open width; Apparatus for — A. Duverger and A. Renion. Fr. Pat. 392,693, July 25, 1908.

INSIDE an apparatus for dyeing fabrics in the open width, and below the working level of the dye-liquor, a tube is arranged which is connected with an aspirator and is provided with an opening or a number of openings of

variable size. These openings are so arranged that when the fabric is travelling through the dye-liquor from one roller to another, dye-liquor is aspirated through the cloth into the interior of the tube, this liquor being eventually returned into the vat. In this way thorough penetration of the fabric by the dye-liquor is ensured.—P. F. C.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Absolute sulphuric acid; its preparation from sulphur trioxide and water; its specific electric conductivity and that of more dilute acid. [Determination of the strength of strong sulphuric acid.] D. M. Lichty, J. Amer. Chem. Soc., 1908, 30, 1834—1846.

By repeated distillation over phosphoric oxide in an apparatus previously exhausted to about 30 mm., sulphur trioxide has been prepared pure and with a permanently low melting point (unpolymerised). From this pure trioxide and water, weighed in sealed bulbs and cautiously mixed in stoichiometrical proportions, absolute sulphuric acid (H_2SO_4) has been obtained. The specific electric conductivity of this acid at 25°C. is 0.01041 reciprocal ohm, and the conductivity is raised by the addition of water or of the fuming acid, even in traces. Measurement of the specific conductivity is found to be the most accurate way of determining the strength of pure acid containing not more than 5 per cent. of water, and a table of conductivities is given. By the addition of water or fuming acid to absolute sulphuric acid, its freezing point (10.43—10.45°C.) is depressed.—E. SORX.

Sodium bicarbonate; Dissociation of —, Soury. Compt. rend., 1908, 147, 1296—1299.

As the dissociation of sodium bicarbonate, not only carbon dioxide but also water is evolved; and as there are therefore three constituents concerned, there must be four phases if the system is to have but one degree of freedom, or show a fixed tension of dissociation at a fixed temperature. The author mixed 27.54 grms. of the dry bicarbonate (which if completely dissociated would evolve 3660 c.c. of carbon dioxide at 0°C. and 760 mm.) with 5.4 grms. of water, and heated to 100°C. The tension, 1600 mm., went down gradually as carbon dioxide was removed, till when 260 c.c. had been removed it reached 800 mm., at which it remained till about 1800 c.c. had been removed; then it fell again to 650 mm. when 2560 c.c. had been removed and was constant up to the removal of 3210 c.c. According to the author, the figures point to the formation of $3\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{CO}_3 \cdot 4\text{H}_2\text{O}$, which at first dissolves in the water, but begins to crystallise from the saturated solution and form a second solid phase when the period of constant tension begins. Complete conversion into this, and disappearance of the bicarbonate, occurs when 1830 c.c. of carbon dioxide have been evolved, and this agrees with the position of the end of the period of constant tension. Normal carbonate is now formed, and when this in turn saturates the water present, and forms a second solid phase, the second period of constancy begins. (J. T. D.)

Ammonia; Synthesis of — by means of peat. H. Wolterreck. Compt. rend., 1908, 147, 1402—1403.

The author has continued his investigations on the synthesis of ammonia by means of peat. The results are shown in the following table; in the first three experiments, 50 grms. of peat were employed, and in each of the last two, the residue from the preceding experiment, after taking 2 grms. for the determination of nitrogen, and making up to 50 grms. with fresh peat. Each experiment extended over four hours at 450°C., air saturated with water vapour at 80°C. being passed through at the rate of 14 litres per hour.

	1.	2.	3.	4.	5.
Dry peat taken	36.4	36.4	36.4	39.9	41.6
Dry peat consumed	21.4	21.2	21.4	19.0	15.0
Ammonia produced	0.571	0.561	0.560	0.587	0.471
Total nitrogen in peat taken	0.820	0.820	0.820	0.995	1.047
Nitrogen in residue	0.410	0.419	0.415	0.572	0.731
Nitrogen in ammonia produced	0.470	0.462	0.461	0.483	0.388
Total nitrogen recovered	0.880	0.881	0.876	1.055	1.119
Excess of nitrogen recovered over that present in peat	0.060	0.061	0.056	0.060	0.072

It will be noted that the residue contains a considerably larger percentage of nitrogen than the original peat; if however the treatment be continued for 6 hours instead of 4 hours, the percentage of nitrogen in the residue is less than in the original peat. The author is endeavouring to ascertain the manner in which the nitrogen is accumulated in the peat during the earlier stages of the process. (A. S.)

Colloidal barium sulphate. E. Feilmann. Trans. Faraday Soc., Dec., 1908. (Advance proof.)

Barium chloride solution is added to an aqueous solution of sodium sulphate and alkali-casein. The colloidal barium sulphate is precipitated from the mixture with acetic acid, washed by decantation with distilled water, and redissolved in very dilute alkali. The solution so obtained may be evaporated to dryness, and then yields a translucent, horny solid, soluble in water. Thus on adding to 230 c.c. of alkali-casein solution, first 200 c.c. of a solution containing 14.2 grms. of anhydrous sodium sulphate, and then, with stirring, 100 c.c. of a solution containing 24.5 grms. of barium chloride crystals, a thick creamy liquid was obtained which, when treated as described above, yielded a soluble dry product containing 56.7 per cent. of barium sulphate.—E. F.

Sulphur dichloride; Action of —, on metalloids and metals. P. Nicolardot. Compt. rend., 1908, 147, 1304—1306.

Among the non-metals, sulphur and selenium dissolve readily in sulphur chloride even in the cold. White phosphorus also dissolves, without effervescence, whilst red phosphorus, which also dissolves, causes a lively effervescence. Arsenic is but slightly attacked, and the action ceases without the substance being dissolved, but antimony dissolves readily. Carbon, silicon, and boron are quite unaffected. Among the metals, only tin, aluminium, mercury, and iron are attacked. In the case of iron, ferrous sulphide and chloride are both formed, in proportions depending on the quantity of sulphur chloride present, but no ferric chloride is produced in any case. (J. T. D.)

Chlorazide, NaCl . F. Raschig. Ber., 1908, 41, 4194—4195.

On mixing together solutions of molecular proportions of sodium azide, N_3Na , and sodium hypochlorite, no reaction takes place, but if the mixture be acidified, even with a weak acid such as acetic acid or boric acid, it becomes yellow, and a colourless gas, having an odour resembling that of hypochlorous acid, is evolved. This gas explodes violently in contact with a flame or a glowing splinter; it sometimes also explodes spontaneously, shattering the containing vessel, even when not exposed to intense light. It is somewhat soluble in water; it is also absorbed

by sodium hydroxide solution, and the resulting solution liberates iodine from an acidified solution of potassium iodide. In this reaction 1 mol. of hydrogen chloride and 1 mol. of hydrogen azide are formed for every 2 atoms of iodine liberated, hence it is concluded that the explosive gas is chlorazide, N_3Cl . When the gas is absorbed in sodium hydroxide solution, sodium azide and sodium hypochlorite are formed, for the resulting solution gives with silver nitrate, first a greyish-white precipitate of silver azide and then a black precipitate, probably basic silver hypochlorite, similar to that given by an alkaline solution of sodium hypochlorite.—A. S.

Sodium nitrate statistics, Shipments, consumption, stocks, and prices, from 1906 to 1908. W. Montgomery and Co., London. Dec. 31, 1908. [T.R.]

PATENTS.

Ammonia; Manufacture of —. F. W. Frerichs, St. Louis, Mo. U.S. Pat. 905,415, Dec. 1, 1908.

AMMONIA and volatile ammonium compounds, obtained by the distillation of ammoniacal liquors, are combined with acid ammonium sulphate, and the normal sulphate, thus formed, is heated so as to give ammonia again and acid ammonium sulphate or ammonium pyrosulphate to be re-used in the process. When ammonium sulphate contains nitrogenous and other organic carbon compounds, it may be purified by heating the impure salt in a blast of air to such a temperature that the volatile carbon compounds are volatilised or oxidised and the nitrogenous compounds are converted into ammonium sulphate by reacting with the sulphuric acid of the ammonium salt.—F. SODX.

Alumina and silica; Composition [refractory matter containing] —. F. J. Tone, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 906,339, Dec. 8, 1908.

THE patent is for a homogeneous product obtained by fusing a mixture of alumina and silica, containing more than 5 and less than 35 per cent. of the latter (*i.e.*, less than the proportion present in the compound, $Al_2O_3 \cdot SiO_2$) and substantially free from basic impurities; it is characterised by great hardness and toughness, and is very refractory.—F. SODX.

Acetates, especially sodium acetate; Electro-chemical manufacture of —. C. H. Jacob. First Addition, dated Sept. 27, 1907, to Fr. Pat. 383,595, Jan. 12, 1907 (this J., 1908, 341).

ALCOHOLIC liquors produced by the saccharification and fermentation of starchy or other substances, are, prior to distillation, electrochemically oxidised to acetic acid

by means of a catalytic agent at a temperature of 40° C., as described in the main patent.—F. R.

Chlorates; Purification of —. R. Gartenmeister. Fr. Pat. 392,604, July 24, 1908. Under Int. Conv., June 27, 1908.

CHLORATES manufactured electro-chemically are contaminated by an impurity which renders their use dangerous (this J., 1908, 806). By prolonged boiling with about the calculated amount of sufficiently dilute hydrochloric acid, this impurity is destroyed, no appreciable quantity of chlorate being decomposed. The chlorine compounds formed may be removed by long boiling, or more rapidly by adding a little alcohol or other suitable reducing agent.—F. SODX.

Tin paste residues; Conversion of — into stannic chloride. A. E. Nicolle. Fr. Pat. 392,615, July 24, 1908. Under Int. Conv., July 6, 1908.

THE tin paste obtained as a residue in dye works may be converted directly into stannic chloride by treating the moist paste with excess of hydrochloric acid (15–20 per cent. above the calculated quantity), concentrating to 45° B., and heating the liquid, which must still contain the same excess of acid, for 6 hours in an autoclave at 5–6 atmospheres pressure. Any organic matter is next destroyed by chlorine, and the tin necessary to convert the excess of acid, in the presence of chlorine or other oxidiser, into stannic chloride is added. If grease be present, the solution should be filtered before concentrating, and any considerable proportion of iron should be removed by means of ferrocyanide.—F. SODX.

Stannic oxide; Preparation of —. H. Müblinghaus. Fr. Pats. 392,805 and 392,806, July 30, 1908.

MATERIAL containing tin, such as dross, waste tin, or ores, is heated in a small blast furnace or other furnace with a large excess of coke, the materials being introduced in alternate layers and chalk or dolomite added to raise the fusion point. A permanent zone of coke collects in the lower part of the furnace, in passing through which reduction of the molten material is completed; the liberated tin is oxidised by a blast of hot air, the oxide being carried out at the top of the furnace with the blast. A more complete yield is obtained, however, if the oxide formed does not pass through the upper layers of material, and, for this purpose, the fusion may be carried out in a separate furnace, any suitable substance being added to bring the melting point to about 1300–1500° C., and the molten material is then run into the main furnace which is charged with coke and supplied with a blast of hot air, preferably under pressure. The last traces of tin, down to 0.18 per cent., may be recovered as oxide by this arrangement.

—F. SODX.

Copper sulphate; Manufacture of —. P. C. J. Coste, Fr. Pat. 392,617, Jan. 14, 1908.

THE invention relates to an arrangement of apparatus for the manufacture of copper sulphate from crude copper oxide and sulphuric acid. In the reacting vessel the acid and sifted oxide are heated and agitated by the injection of superheated steam and air. The supersaturated solution of sulphate is run out to crystallise, and the mother liquor is heated by contact with the pipe in which any escaping acid vapours are condensed; it is then filtered and returned to the reacting vessel. The insoluble matter is run out from the latter at intervals and washed by treatment with water and steam. Gravitation is utilised as far as possible in transferring material from one part of the apparatus to another, and the waste heat is used for preheating the raw materials. — F. SODX.

Hydrosulphides of the alkaline-earth metals; Manufacture of —. S. Coulier. Fr. Pat. 392,671, July 16, 1908.

THE hydrosulphides of the alkaline-earth metals may be prepared by treating the corresponding oxides, hydroxides, or sulphides with ammonium sulphide or with hydrogen sulphide in the presence of ammonia, the liberated ammonia being subsequently removed and used again. Solutions strong enough to crystallise may be obtained in this way. Contact with air should be avoided. — F. SODX.

Alkali and other silicates; Manufacture of — [in the electric furnace]. Soc. Electrometallurgique de Saint-Béron. Fr. Pats. 392,945 and 392,946, Aug. 3, 1908.

CLAIM is made for the use of an electric furnace in the manufacture of alkali silicates, and for the products thus obtained, which are of exceptional purity and of definite composition. Simple or mixed silicates of the type M_2SiO_3 or $M_2Si_2O_7$ may be prepared by the process in a crystalline state. Sulphates and bisulphates are converted into silicates by fusion with silicious matter in the electric furnace, without the customary addition of carbon; the acid vapours liberated may be utilised for the manufacture of sulphuric acid. — F. SODX.

Potassium ferrocyanide; Manufacture of — from sodium ferrocyanide and potassium chloride. C. Petri. Fr. Pat. 393,003, Aug. 6, 1908. Under Int. Conv., Aug. 7, 1907.

SODIUM ferrocyanide is dissolved in such a quantity of water that the solution will further dissolve, on boiling about 1·7 times the quantity of potassium chloride required to react with the ferrocyanide. After solution of the two salts, the liquid is allowed to cool, when about 70 per cent. of the ferrocyanide is deposited as the potassium salt in marketable form. From the mother liquor, on cooling to -10° to -20° C., a further 18–20 per cent. of the potassium ferrocyanide is obtained, which requires one crystallisation to free it from potassium chloride. By dissolving more potassium chloride in the new mother liquor, another 4–6 per cent. of potassium ferrocyanide, mixed with chloride, are deposited, and the residual ferrocyanide may be recovered from solution by precipitation as the double salt of calcium and potassium. The first yield of crystals may be increased to 75 per cent. by effecting the solution under pressure, at a temperature above 100° C., which allows a larger proportion of potassium chloride to be used for saturating the liquid. The method is claimed to remove the difficulty hitherto experienced in converting sodium ferrocyanide into the potassium salt by means of potassium chloride (this J., 1898, 98, 103). — F. SODX.

Moist chlorine; Process of dehydrating —. E. A. Sperry, Brooklyn, N.Y. U.S. Pat. 905,602, Dec. 1, 1908.

MOIST chlorine, contained in a mixture of gases, is refrigerated in a series of chambers, so that "chlorine hydrate" is deposited and the excess of chlorine and other gases pass out of the chambers. Some of the chambers are then disconnected from the system and the contents treated for the liquefaction of the hydrate and the separation of the chlorine and water. — F. SODX.

Silicon; Preparation of —. F. J. Tone, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 906,338, Dec. 8, 1908.

ORES, such as aluminium silicate, containing aluminium and silicon, and substantially free from iron compounds and "basic metalliferous materials," are mixed with sufficient carbon to reduce the silicon only to the elementary form. The mixture is heated electrically to a temperature sufficient to bring about reduction and to fuse the alumina, which is then separated from the silicon. — F. SODX.

Hydrogen; Preparation of — by the decomposition of water. P. Mauriceau-Beaupré. Fr. Pat. 392,725, July 27, 1908.

PURE hydrogen is conveniently and cheaply prepared by the action of water on a mixture of pure aluminium filings with 1–2 per cent. of mercuric chloride and 0·5–1 per cent. of potassium cyanide. The mixture must be kept quite dry. To prepare hydrogen, it is treated with an equal weight of water, which causes considerable rise of temperature in a few seconds, and then water is added regularly, so as to keep the temperature at about 70° C. An advantage of the process is that neither the reacting substances nor their products have any corrosive action. Pure aluminium hydroxide is obtained as a by-product. — F. SODX.

Stannic chloride; Process for producing —. The Columbia Process Co. Fr. Pat. 392,618, March 12, 1908. SEE U.S. Pat. 884,756 of 1908; this J., 1908, 749. — T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

PATENTS.

Metallisation of vitreous, porcelain, earthenware and the like surfaces so that metal or metallic alloy may be electro-litically deposited upon such surfaces. Q. Marino. Eng. Pat. 17,743, Aug. 3, 1907.

THE grey substance containing finely-divided silver produced by adding cuprous oxide to a solution of silver nitrate is dissolved in hydrofluoric acid, and the solution so obtained is applied to the roughened surfaces to be treated. While still wet the surface is dusted with a mixture of metals, such as copper and zinc, or with one metal only, such as zinc, in a finely-divided state. The silver and copper are thus reduced from the solution and form a thin film over the surface, on which the metal or metallic alloy may be deposited. — O. F. H.

Glass articles; Fire glazing or finishing of —. M. Cummins and C. W. Schwenzfeier, Manchester. Eng. Pat. 390, Jan. 7, 1908.

GLASS articles are fire-glazed and finished by exposing them, mounted in carriers, to the action of an electric arc generated between two carbon rods, inclined so that the

are is at the top. The carbon rods are balanced by a weight, which is coupled to the movable core of a vertical electro-magnet, so that the carbon rods are brought together when the current is switched off, and separated when the current is started. The carbon rods may be mounted on a centrally or excentrically revolving frame, according to the articles to be finished.—A. G. L.

Window glass machines: Continuous draw vacuum—
H. D. Hershey, Latrobe, U.S.A. Eng. Pat. 19,827,
Sept. 21, 1908.

A NUMBER of cylinders of glass, 49, are drawn continuously vertically upwards from the clearing tank, 17, of a glass furnace, 16. Each cylinder is started by a bait attached to a drawing cylinder, which is subsequently detached. The lower part of each cylinder is surrounded by a metal casing, 19, supplied with an asbestos cover, 29, held tightly against the cylinder. The air within this casing and around the cylinder is continuously exhausted by means of a blower, through the pipe, 20, and the perforated ring, 24. Air under atmospheric pressure is at the same time admitted to the interior of the cylinder from above. The weight of each cylinder is supported, and the cylinder is pushed upwards, by four friction wheels, 32 (two only shown), which are coupled to one shaft by three gear-wheels and pinions so as to revolve simultaneously. The metal rim, 35, of each wheel is covered with asbestos and shaped so as to fit the cylinder; the rim is supported on the hub, 39, by a number of metal rings, 41, set at slightly different angles, so as to allow the rim to assume an excentric position with regard to its shaft. In this way the wheels are made to tightly engage cylinders of different sizes. Sections of the cylinders, 49a, are severed from time to time and rolled into window glass in the usual way.—A. G. L.

Mirroring glass or like surfaces: Process of—

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland cement: Free lime in—
A. H. White. J. Industrial and Eng. Chem., 1909, 1, 5—11.

THE author describes a microscopic test for free lime in Portland cement, based on the formation of crystalline calcium phenolate which has a characteristic appearance when examined in polarised light. The reagent used consists of 5 grms. of crystallised phenol dissolved in 5 c.c. of nitrobenzene, with the addition of two drops of water. The test is made by placing 2 or 3 mgrms. of the finely powdered cement on a slide, adding a drop of the reagent, pressing down with a cover glass, and placing at once under the microscope with crossed nicols at a magnification of about 80. Cement is only feebly refracting, but within a few minutes, if any free lime be present, brilliant points begin to show, which develop in 15 minutes into clusters of radiating needles; at the end of 2 hours, the needles may be 0.1 mm. long. The formation of crystals of phenol is prevented by the moisture present in the reagent and absorbed from the air as the solvent on the slide evaporates. Calcium hydroxide responds to the test as well as calcium oxide, but no other substance has been found to do so. Phenolphthalein may be added to the reagent, when pink spots appear round the particles of lime, but in this case magnesia also will react. Comparison of this test with the boiling test showed good agreement, the microscope test being the more delicate. Cements which do not give the crystals within an hour, contain no more than a trace of free lime. Experiments with this test on unsound cements showed the cause of the unsoundness to be presence of free lime, due in most instances to coarse grinding of the raw materials.—J. H. J.

Cement: Influence of electrolytes on the setting time of—
Rohland. Stahl u. Eisen, 1908, 28, 1815—1819.

THE author shows that the action of electrolytes on the setting-time of slag-cement is, qualitatively at least, the same as on that of Portland cement. Thus, sodium chloride, added in small quantity, has no action on either cement; sodium carbonate causes an acceleration; calcium chloride, added in small quantity, delays setting, but added in large amounts, accelerates it. Sodium sulphate, potassium bichromate, and borax delay the setting of both cements, but a larger proportion of sodium sulphate is necessary to affect slag cement than Portland cement. Dissolved electrolytes have a greater influence than the solid salts; the difference in the action is especially marked with the less soluble salts, e.g., borax.

—A. G. L.

PATENTS.

Kilns: Gas-fired—[for bricks, pottery, etc.]. G. Feun
and C. F. Priest, Dudley. Eng. Pat. 2905, Feb. 10, 1908.

THE kiln is heated by means of gas delivered from a series of small gas-producers which take the place of the usual "fire-holes." A steam main encircles the kiln, and branch pipes extend downwards from the main, one into each gas-producer. Each branch pipe consists of independent upper and lower parts, with an air-gap between; the steam in passing from the upper to the lower part, draws in air, and the mixture of air and steam is delivered below the grate of the producer. The air supply for the combustion of the gas from the producers is preheated

by passing (by natural draught) through zig-zag flues, in the inner lining of the kiln. One of these air-flues is provided for each gas-producer, and the gas-exit pipe of the latter passes through the lower part of the corresponding air-flue. The gas and heated air mingle in a passage between the lining of the kiln and the flash-wall, and thence pass into the interior of the kiln.—A. S.

Artificial stone; Manufacture of ——. C. A. P. Turner. Minneapolis, U.S.A. Eng. Pat. 13,941, July 1, 1908.

THE sand to be used for making moulds for artificial stone is treated with a saturated solution of sodium chloride, and is preferably also mixed with 20 per cent. of marl. The surface of the sand mould is sprayed with soap solution, whilst alum solution is added to the liquid stone composition. Potassium chloride or calcium chloride may be used instead of sodium chloride. —A. G. L.

Wood; Apparatus for use in treating ——. S. S. Williams. Providence, R.I. U.S. Pat. 904,589, Nov. 24, 1908.

THE apparatus consists of a closed chamber provided with an air-tight door in one side. Within the chamber are placed steam coils, which are rigidly held against the sides and top, so as to strengthen the latter; these steam pipes are provided with valves which can be operated from outside the chamber, and which admit steam to the inside of the latter. Below the chamber, and communicating with it by two valved pipes, are placed two tanks, a larger one for fresh treating liquid, and a smaller one for used liquid from the chamber. Means are also provided for exhausting the chamber, so as to cause the liquid from the larger tank to rise into it, as well as means by which the liquid purified in the smaller tank is returned to the larger one.—A. G. L.

Refractory material for furnaces and crucibles. W. Rippey. Alleghenny, Pa. U.S. Pat. 905,295, Dec. 8, 1908.

SAND, cement, and water are moulded and heated until incipient fusion of the sand takes place.—A. G. L.

Silicates; New application of metallic ——. to the maintenance of roads. Soc. Electrométallurgique de Saint-Béron and A. Jouve. Fr. Pat. 393,135, Aug. 3, 1908.

ROADS, especially of macadam, wood blocks, or concrete, are sprinkled with a solution of soluble metallic silicates, to which fluorides or fluosilicates may be added, for the purpose of alloying dust.—A. G. L.

Gypsum; Apparatus for burning — in pieces and in powder. J. H. Monbeig. Fr. Pat. 393,226, Oct. 19, 1907.

(1). HOT gases, generated in two separate fire-places, pass through two openings into a large chamber containing the gypsum to be burnt. Large pieces of the gypsum are arranged at the bottom of the chamber, close to the two openings, so as to form two passages which the gases traverse, smaller pieces of gypsum, and powder, being placed on top of these large pieces. The chamber is emptied from time to time by means of trucks running on rails which pass through a large opening into the chamber. (2). Gypsum is continuously burnt in a long kiln of semi-circular section, which is given a reciprocating movement about its long axis. This kiln is placed partly above a fire-grate, partly above the flue leading the gases from the latter to the chimney. The kiln is charged from a hopper (which is above the fire-grate end of the kiln) and discharged through a shoot at the other end. The fixed walls of the furnace are curved inwards towards the movable kiln where they touch the latter, so as to allow the kiln to oscillate without permitting air to enter the furnace.—A. G. L.

Blast-furnace slag; Treatment of — for production of hydraulic cement. B. Grau, Kratzwieck, Germany. U.S. Pat. 905,813, Dec. 1, 1908.

A JET of steam charged with lime is blown against a stream of liquid slag issuing from a furnace, with sufficient force to disintegrate the slag. The mass then falls a sufficient distance and cools gradually, after which it is ground.—A. G. L.

Cement and the like; Drying apparatus for ——. Bühler Frères. Fr. Pat. 392,743, July 27, 1908. Under Int. Conv., Aug. 31, 1907.

THE apparatus consists of two tunnels placed side by side, through which hot gases are drawn into a moisture-collecting chamber by means of a fan, etc., the cement, clay, etc., to be dried being placed in the tunnels. The valves operating the doors at each end of the tunnels are connected with the dampers regulating the admission and exit of the hot gases by means of a system of pulleys and cables in such a way, that the opening of either door of one of the tunnels simultaneously closes the dampers between this tunnel and the moisture-collecting chamber, and also the dampers regulating the hot gas supply to this tunnel, so that the working of the other tunnel is not interrupted, and cold air is not sucked into the first tunnel.—A. G. L.

Hydraulic binding agents containing aluminates and silicates; Improvement of — by addition of barium salts. Königshofer Zement Fabr., A.-G., Ger. Pat. 204,700, May 15, 1907. Addition to Ger. Pat. 204,699.

FOR the improvement of hydraulic cements prepared from blast-furnace slag and similar materials, an addition of barium carbonate was proposed in the main patent (see Fr. Pat. 370,939 of 1906; this J., 1907, 257). It has now been found that other compounds which react to yield insoluble sulphates, e.g., compounds of lead, strontium, and the like, may be used in place of barium carbonate.—A. S.

Cement; Process for making ——. H. Colloseus. Fr. Pat. 392,734, July 27, 1908.

SEE Eng. Pat. 25,795 of 1907; this J., 1908, 841.—T. F. B.

Plaster, cement, or similar materials; Process for mixing — with water. Sackett Plaster Board Co. Fr. Pat. 392,830, March 31, 1908.

SEE Eng. Pat. 7091 of 1908; this J., 1908, 751.—T. F. B.

Cement, hydraulic lime, and dry mortar mixtures; Process for protecting — against moisture during storage. J. Junge. Fr. Pat. 392,817, July 31, 1908.

Alumina and silica; Composition [refractory material] containing ——. U.S. Pat. 906,339. See VII.

Aluminium ores; Process of smelting — and method of treating aluminium silicate. U.S. Pat. 906,172 and 906,173. See X.

X.—METALS AND METALLURGY.

Patio [silver extraction] process; The ——. C. P. Duarte. J. Chem. Met. and Min. Soc., S. Africa, 1908, 9, 105—110.

THE author describes in detail the patio process of silver extraction, which has altered but little since the 16th century, but which will probably have to give place to cyaniding. He discusses at some length, the various theories of the chemical reactions that take place, and gives as his opinion that the sodium chloride reacts with the copper sulphate of the "magistral" to form copper chloride, which then chloridises the silver sulphide. The silver chloride is reduced by the mercury to the metallic state and becomes amalgamated, calcium being formed at the same time by the liberated chlorine.—F. R.

Aluminium; Analysis of powdered ——. E. Kohn. Abstr. Compt. rend., 1908, 147, 1293—1296.

ALL aluminium powder contains a notable proportion of oxide. The author has determined the metallic aluminium in a carefully prepared sample, both by combustion of the hydrogen evolved on dissolving in acid, and weighing the water produced, and also by dissolving in ferric sulphate solution at 100° C., and titrating the ferrous salt formed; the average of many concordant determinations was 92.95 per cent. Complete analysis

of another sample gave the following percentage results:—Metallic aluminium, 92.499; silicon, 0.418; silica, 0.259; iron, 0.613; nitrogen, 0.152; carbon, 0.310; sodium, 0.006; aluminium insol. in acid, 0.024; alumina, by difference, 5.719. A check determination of the total aluminium agreed with the result calculated from the above analysis.—J. T. D.

Silico-thermal experiments. P. Askenasy and C. Ponnaz. Z. Elektrochem., 1908, 14, 810—811.

If with a finely-powdered mixture of barium peroxide and silicon, reaction be started as in Goldschmidt's aluminothermic process, it proceeds with such violence that the material is entirely expelled from the crucible, but it may be moderated by using coarser raw materials. With 50 parts of the peroxide to 4 parts of 90 per cent. silicon, the reaction product was a silicate, which was completely volatilised. On increasing the proportion of silicon to 15 parts, a silicide containing 30 per cent. of barium was obtained. This decomposed water with evolution of hydrogen, and hydrochloric acid with production of hydrogen silicide. This silico-thermal process can be used for melting iron, copper, etc., and for the reduction of oxides such as chromium oxide. The silicon may be replaced by ferrosilicon or titanium silicide, Ti_2Si_3 . At the present time, 90 per cent. silicon costs about 80 Pf. per kilo.—A. S.

Alloys of sodium and potassium; New method of formation of —. G. F. Jaubert. Ber., 1908, 41, 4116—4120.

By the action of sodium on potassium hydroxide or of potassium on sodium hydroxide, liquid alloys of the two metals, containing up to nearly 80 per cent. of potassium are obtained. The reaction is effected in a crucible under a layer of paraffin wax, or *in vacuo*, and according to the temperature and to the proportions of the reacting substances, the products contain from 62.9 to 77.2 per cent. of potassium, corresponding to the formulae, NaK and NaK_2 ; the yields are almost theoretical. The alloy, NaK_2 , is prepared on a commercial scale at Clavaux (Isère), France, by heating together sodium and anhydrous potassium hydroxide to 350° C. in an iron autoclave.—A. S.

Cobalt and its alloys with antimony; Action of antimony trichloride on —. F. Duclleuz. Compt. rend., 1908, 147, 1048—1050.

COBALT decomposes antimony trichloride above 600° C., giving cobalt chloride and an alloy of cobalt and antimony. By passing antimony chloride vapour over powdered cobalt below 1200° C., until the composition of the alloy remains constant, the non-magnetic compound, $CoSb$, is obtained; by the further action of the chloride this compound is decomposed, antimony being deposited and cobalt chloride formed, and above 1450° C. antimony is lost by volatilisation. Above 1200° C. the alloy formed contains less antimony and is attracted by a magnet. The alloys of cobalt and antimony have also been prepared directly in an atmosphere of hydrogen; incandescence takes place when a mixture of the powdered substances is heated to 500° C. The compounds, $CoSb$ (m. pt. about 1200° C.) and $CoSb_2$ (m. pt. about 700° C., with decomposition), have been obtained in this way. They are crystalline powders which, on heating, react vigorously with oxygen, sulphur, and chlorine, are readily attacked by nitric acid, but are scarcely affected by hydrochloric acid, and only slowly by fusion with alkalis or alkali carbonates. Alloys containing more than 67.04 per cent. of antimony are rapidly converted at 1200° C., in a stream of hydrogen or antimony chloride vapour, into the compound, $CoSb$.—F. Soub.

Ferrosilicon; Poisonous effects of vapours from —. "Times," Dec. 22, 1908. [T.R.]

At the inquest on the bodies of five Russian emigrants on the steamer "Ashton," which carried nine tons of ferrosilicon from Antwerp to Grimsby, it was stated that the ferrosilicon contained carbon, arsenic, and phosphorus, and that, in presence of moist air, it generated the hydrides of arsenic and phosphorus and also acetylene and hydro-

gen. The quantity of ferrosilicon carried would generate 110 cu. ft. of the gases in 24 hours. The material was carried in barrels in the hold, immediately below the emigrants' berths, a hatchway connecting the places; the hold was stated to be dry.

Solder used for tinned goods; Limit of lead in — for importation into Uruguay. Board of Trade J., Dec. 31, 1908. [T.R.]

SINCE JAN. 1, 1909, the importation into Uruguay of preserves in tins, which are closed with solder containing more than 5 per cent. of lead, has been prohibited. The Uruguayan Government has consented to exempt from this regulation all British tinned goods shipped to Uruguay before Dec. 31, 1908.

PATENTS.

Steel alloys; Manufacture of —. J. R. Crawford, Bushey, Herts. Eng. Pat. 21,356, Sept. 26, 1907.

STEEL alloys are obtained by adding the alloying metal in the form of carbide or ferro-carbide to the steel, most of the carbon of the carbide being eliminated by oxidation. In certain cases, however, the alloying metal is preferably added as nitride, the nitrogen escaping as gas. The formation of blow-holes may be prevented by the addition of aluminium, etc. Suitable nitrides are formed by titanium, lithium, tantalum, vanadium, and uranium.

—A. G. L.

(1). *Metallurgical process* (2). *Manganese and ferro-manganese; Process of making —.* A. G. Betts, Troy, N.Y. U.S. Pats. 905,280 and 905,281, Dec. 1, 1908.

(1). METALS are obtained from molten slags by the addition of silicon or a silicon alloy to the latter. (2). A slag containing iron and manganese is treated with sufficient silicon to reduce the iron, after which manganese is reduced by the addition of a further quantity of silicon.

—A. G. L.

Converter; Regulation of the temperature and reactions in the —. Ges. f. Linde's Eismaschinen A.-G. Ger. Pat. 204,407, July 17, 1907.

THE regulation is effected by varying the oxygen-content of the air blast. Supplies of oxygen and nitrogen are provided so that either of these gases, alone or mixed with air, can be blown into the converter as desired. For example, if it be desired to shorten the duration of blowing, so that larger quantities of pig-iron can be treated, or a larger proportion of scrap used, oxygen is added to the air blast. If it be desired to lower the temperature in the converter, or to prevent excessive oxidation of the iron, nitrogen is added to the blast.—A. S.

Furnace for the cementation of objects of iron, steel, or steel alloys by means of compressed gases. Soc. Anon. Italiana Gio. Ansaldo Armstrong and Co. Fr. Pat. 392,960, Aug. 5, 1908.

THE furnace is intended for the cementation of iron or steel objects, by means of gases such as hydrocarbons, carbon monoxide, etc., at high pressures and temperatures. The cementation chamber enclosed within the furnace is hermetically sealed, with the exception of inlet and outlet tubes for the gases. By means of tuyères, the pressure within the exterior furnace is maintained sensibly equal to that within the chamber, a valve being provided for the gas outlet at the top.—C. A. W.

Iron; Manufacture of malleable — from cast iron rich in both silica and phosphorus. O. Massenez. Fr. Pat. 393,325, July 21, 1908.

THE process is adapted to cast irons containing more than 1 per cent. of silica and phosphorus respectively, and has the advantage of giving a slag very rich in the latter element. The metal is oxidised in a converter with basic lining, lime and iron oxide being added in such proportions that the resulting slags are of too acidic a nature to combine with any appreciable amount of phosphoric acid. The silicon having been completely oxidised, the

very liquid slag is run off, and lime, in amount equal to two-thirds that required to form the tetrabasic phosphate, added. The process is then continued until the greater part of the phosphorus has been oxidised, the metal being afterwards transferred to a furnace with basic hearth, where the dephosphorisation is completed in the presence of basic oxides. In order to prevent the solidification of the metal in its passage from the converter, it is advisable to add a small amount of carbon before the transference. In any case, the metal is finally deoxidised and recarburised in the usual way. —C. A. W.

Zinc; Separation of — from its ores and compounds. W. Hommel and H. L. Sulman, London. Eng. Pat. 23,901, Oct. 29, 1907.

The invention constitutes an improvement on Eng. Pat. 21,672 of 1906 (this J., 1907, 1144). If the zinc ore used is deficient in sulphur, iron pyrites or other material rich in sulphur is added to it, and the whole roasted, the sulphur dioxide given off being pumped under pressure into closed vessels containing water. The roasted ore is then strongly heated, so as to volatilise zinc oxide, which is condensed in a series of chambers. The impure zinc oxide, containing lead, etc., from the chambers nearest the furnace, is next treated in closed vessels under pressure with the solution of sulphur dioxide obtained as above. The solution of zinc bisulphite obtained is separated from the insoluble lead compounds, etc., and normal zinc sulphide is precipitated, by treating the solution with pure zinc oxide from the chambers furthest from the furnace, by exposing it in a vacuum, or by a combination of both methods. The zinc sulphite obtained is finally calcined to zinc oxide. —A. G. L.

Acid metallic solutions; Treatment of — for the extraction of metals [zinc]. P. D'Alton-Shée, Fr. Pat. 392,867, Oct. 8, 1907.

THE process may be applied to the separation of zinc from other metals in a solution, such as that obtained by the action of acid on a roasted blende. The solution having been previously filtered, is mixed with a small quantity of sodium hypochlorite, in order to oxidise any iron, chromium, or manganese, which are afterwards precipitated by the addition of zinc oxide or hydroxide to the hot solution. The zinc is finally precipitated by the addition of ammonia, not in excess, according to the reaction: $3\text{ZnSO}_4 + 4\text{NH}_4\text{OH} = (\text{NH}_4)_2\text{SO}_4 + (\text{NH}_4)_2\text{SO}_4 \cdot \text{ZnSO}_4 + 2\text{Zn}(\text{OH})_2$, the double sulphate being quite insoluble in the excess of ammonium salt. —C. A. W.

Aluminium; Welding or melting objects of —. M. U. Schoop. Eng. Pat. 24,283, Nov. 2, 1907. Under Int. Conv., Oct. 5, 1907.

FLUORIDES such as calcium fluoride, potassium fluoride, or boron fluoride are added to the flux of alkali chlorides described in Eng. Pat. 24,096 of 1907 (see Fr. Pat. 374,089; this J., 1907, 828). —O. F. H.

Aluminium ores; Process of smelting —, and method of treating aluminium silicate. F. J. Tone, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pats. 906,172 and 906,173, Dec. 8, 1908.

ALUMINIUM silicate is mixed with carbon and with a base metalliferous material, the amount of carbon being sufficient to reduce only the whole or a part of the silica present, but none of the alumina, and the quantity of base metalliferous material being such as "to form a disintegrating alloy with the reduced silicon." The mixture is electrically heated so as to fuse the alumina or mixture of alumina and silica, and to reduce the silicon and cause it to combine with the base metal. The mass is allowed to cool and to disintegrate, after which the alumina or alumina-silica, which is claimed to possess great hardness and abrasive properties, is separated from the alloy of silicon. Alternatively, the addition of base metalliferous material may be omitted, in which case one of the products obtained is silicon. —A. G. L.

Aluminium and other metals; Solder for —. C. G. Carroll and W. H. Adams, Fayetteville, Ark. U.S. Pat. 906,383, Dec. 8, 1908.

THE solder consists of calcium and tin or other material possessing sufficient affinity for aluminium and other metals it is desired to join. The function of the calcium in the solder is to reduce the oxide on the surface of the aluminium or other metal. —A. G. L.

Refuse tin ware; Method of and apparatus for cleansing articles of — and for the recovery of solder therefrom. J. W. Evans, Cargo Fleet, Yorks. Eng. Pat. 26,383, Nov. 29, 1907.

THE refuse tin ware is delivered by means of a hopper to one end of a revolving perforated cylinder provided with a spiral worm, by means of which the articles are tumbled forward through the cylinder until they fall, freed from tin, into a receptacle placed at the other end, from which they are discharged at intervals by opening a slide. At this end, beyond the receptacle, is placed a fire-grate, from which reducing gases pass into the cylinder, heating it to a dull red heat. The walls of the cylinder are perforated, and it is completely enclosed within an outer brick chamber. Below the cylinder is placed a tank of water, into which melted tin, solder, iron oxide, and dirt fall through the perforations. By means of inlet and outlet pipes set at the surface of the water in the tank, a constant flow of water is maintained through the latter so as to wash away the dirt. The tin, etc., is from time to time raked out of the tank through an opening near the bottom; it is dried and the iron oxide separated magnetically. —A. G. L.

Ore separating processes. M. Ruthenburg, Lockport, U.S.A. Eng. Pat. 28,191, Dec. 21, 1907.

THE process is applicable to ores and concentrates, e.g., "Elmore concentrates," which cannot be separated by gravitation in water because they are not wetted by it. It consists in separating the separate components by gravitation in a liquid hydrocarbon, e.g., the lighter petroleum distillates, which "wets" the minerals, and dissolves the heavy oil if "Elmore concentrates" are used. —A. G. L.

Concentration of pulverised ore; Apparatus for the —. J. Guinea, Viscaya, Spain. Eng. Pat. 11,762, May 30, 1908.

THE apparatus consists of an inclined table of trapezoidal form, provided with an ore-charging receptacle at the upper corner of the wider part, and a watering pipe along the upper edge. Longitudinal grooves are formed in the surface of the table in its wider portions. The table is given a combined reciprocating and rising and falling movement, in such a way that it descends whilst it advances, and rises on returning. This movement is effected by supporting the table from the middle of a series of bent double-armed levers linked together at their lower ends; the upper ends of the levers are keyed to oscillating shafts, operated from an eccentric disc by means of a connecting rod coupled to an oscillating crank on one of the shafts. —A. G. L.

Metalliferous ores; Process of treating —. F. R. Carpenter, Assignor to The American Iron and Steel Alloys Co., Denver, Colo. U.S. Pat. 904,838, Nov. 24, 1908.

ORES are treated without the use of a flux and without producing a slag, by feeding them on to the top of a molten bath of specific gravity intermediate between that of the metallic constituents of the ore and that of the gangue. —A. G. L.

Annealing furnaces. J. and R. Edwards, Morriston, Wales. Eng. Pat. 15,196, July 17, 1908.

IN addition to the usual bridge of a reverberatory annealing furnace, a second inverted bridge is provided beyond the first. This second bridge extends from the top of the furnace to the bottom, but is made solid only in its upper portion, the lower part being provided with a number of perforations, through which the flame passes, being thereby evenly distributed in the annealing chamber. —A. G. L.

Copper and process for purifying, casting, and alloying the same. A. J. Rossi, Assignor to The Titanium Alloy Manufacturing Co., New York. U.S. Pat. 905,232, Dec. 1, 1908.

MOLTEN copper is purified by the addition of titanium or a titanic compound. The resulting metal, containing not more than a trace of titanium, is also claimed.—A. G. L.

Furnaces; Metallurgical —. L. S. Hughes. Fr. Pat. 392,991, Aug. 6, 1908.

THE furnace is intended for the treatment of pulverised ores, and consists essentially of an upright, cylindrical body of thin sheet iron, with a conical bottom, in which apertures are provided for the admission of air. The gas inlets are arranged on an annular tube surrounding the furnace, just above the conical bottom, and are inclined, so that an ascending flame is produced within the combustion chamber. The ore, fed through a hopper at the side, falls in a thin stream on to a jet of air ascending from the bottom, and is so forced up into the hot zone of the furnace, where it mixes with the flames from the burners. By maintaining a strong current of air through the furnace, the heated products are quickly carried away, so that the temperature within the chamber is never sufficient to fuse the oxidised ore. The powdered material, carried away with the gases, is finally deposited in chambers connected with the conduit. The ash and heavier impurities are separated within the furnace proper, and can be removed through apertures at the bottom.—C. A. W.

Magnesium and its alloys; Melting and casting of — without formation of dross. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 393,080, July 11, 1908.

By adding the metal in only small quantities at a time, the mass in the crucible is never allowed to become completely liquid. In this way the temperature never greatly exceeds the melting point of the metal, and the formation of the oxide and nitride is prevented. Before casting, and in order to obtain the necessary fluidity, the vessel containing the pasty mass is quickly agitated after removal from the fire.—C. A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Silundum, a new product of the electric furnace. F. Bölling. Chem.-Zeit., 1908, 32, 1104—1105.

SILUNDUM, a silicide of carbon, is obtained by heating carbon in an atmosphere of silicon vapour, i.e. by heating carbon with carborundum, to which sand may be added, or with a mixture of sand and carbon, at a temperature of 1700°—1800° C. [Silundum appears to be intermediate between carbon and carborundum]. Carbon articles can, if desired, be converted into silundum on one side, or in places only. The electrical conductivity of silundum is considerably less than that of carbon; it varies, together with the hardness, according to the carbon used and the length of heating in silicon vapour. A rod, 800 mm. in length and 6 mm. in diameter, will carry a current of 4000 watts permanently, and of 8000 watts temporarily. The material is stable in air up to high temperatures; at 1750°—1800° C. silicon vapour is given off and at once oxidised. Molten metals, especially iron, destroy it rapidly; consequently crucibles, etc., should be converted into silundum only on the outside. Silundum cannot be used for making filaments for incandescent electric lamps, on account of the deposition of brown silicon on the glass. The chief use of the new material appears to be as a permanent resistance material for high temperature work.—A. G. L.

Carbon dioxide; Decomposition of — by the silent electric discharge. A. Holt, jun. Chem. Soc. Proc., 1908, 24, 271.

CARBON dioxide, which had been carefully dried by phosphoric oxide, was found to be decomposed to an amount which increased as the pressure of the gas diminished. About 48 per cent. decomposition was obtained under 30 mm. pressure, and about 3 per cent. decomposition under 700 mm. pressure. The amount of decomposition was found to vary with the degree of dryness of the gas, the intensity of the discharge, and the form of ozoniser employed, but in all cases diminished pressure gave greater decomposition. Moist carbon dioxide was found to decompose to a larger extent as the pressure of the gas increased, ranging from 3 per cent. decomposition under 50 mm. pressure to about 14 per cent. under 700 mm. pressure. The weaker the discharge the less gas was decomposed at all pressures. Comparison of these results with those obtained when moist and dry carbon dioxide is decomposed by ultra-violet light, or induction sparks, leads to the conclusion that the silent discharge at low pressures acts chemically, mainly like ultra-violet light, whilst as the pressure of the gas increases, it behaves more and more as though it consisted of actual sparks.

PATENTS.

Ozonising liquids; Apparatus for —. F. Barbary. Eng. Pat. 25,202, Nov. 13, 1907. Under Int. Conv., Nov. 29, 1906.

THE apparatus consists of a series of concentric glass vessels, the central one of which is closed by a glass stopper fitted with glass tubes closed at their lower ends and projecting into the vessel. Metallic pins are fitted into the glass tubes and connected with one of the poles of a powerful induction coil. The liquid is introduced into the central vessel by means of a tube in the stopper, and passes from one vessel to another by holes in opposite sides of successive vessels. The outer vessel stands on pointed pins attached to an insulated metal plate which is connected to the second pole of the induction coil, and at the bottom of this vessel is a funnel-shaped opening connected with a receiver in which a vacuum is created.—O. F. H.

Ozone; Method of producing and utilising —. H. N. Potter, New Rochelle, N.Y., Assignor to Cooper Hewitt Electric Co., New York. U.S. Pat. 905,361, Dec. 1, 1908.

THE method of producing and utilising ozone, consists in passing an electric current between electrodes placed inside a container pervious to ozonising radiation, preventing a dissipation of the ozone by suitable means, and conducting it to a required point.—F. R.

Ozone generator. J. J. E. Donzal. First addition, dated May 26, 1908, to Fr. Pat. 391,368, May 4, 1908 (this J., 1908, 1211).

THE apparatus consists of a central tubular electrode perforated by a large number of holes provided with conically arranged pointed projections, a dielectric composed of a large number of capillary tubes placed at a distance of about 0.5 mm. from the central electrode, an exterior spiral electrode holding together the bundle of capillary tubes, and means for drawing air through the central electrode.—O. F. H.

Electrolysis of liquids; Process for the —. J. Billiter, Aschersleben, Germany. U.S. Pat. 903,951, Nov. 17, 1908.

THE liquid is fed into the upper of two superposed chambers separated by a diaphragm. The electrolyte is heated at or about the level of the electrodes in the upper chamber, and the gases generated are withdrawn by suction from the lower chamber beneath the diaphragm.—O. F. H.

Gases; Process and apparatus for effecting chemical action in —. D. R. Lovejoy, Niagara Falls, N.Y., Assignor to W. E. F. Bradley, New York. U.S. Pats. 904,070 and 904,073, Nov. 17, 1908.

THE mixture of gases is subjected to the influence of a radio-active body and to the action of the electric arc, which is successively formed, elongated, and broken. The apparatus consists of a chamber in which are placed two sets of relatively movable electrodes, by means of which arcs may be successively formed, elongated, and broken. Means are provided for introducing the gases into the chamber, and for subjecting them to the influence of a radio-active body.—O. F. H.

Gases; Apparatus and process for chemically combining —. D. R. Lovejoy, Niagara Falls, N.Y., Assignor to W. E. F. Bradley, New York, N.Y. U.S. Pats. 904,071 and 904,072, Nov. 17, 1908.

THE apparatus consists of a chamber in which electrodes are so mounted that arcs may be rapidly formed between them, elongated, and broken. Means are provided for refrigerating the gases on their way to the chamber, and for liquefying or solidifying the gases. The gases, such as nitrogen and oxygen, are subjected to the action of electric arcs, thus successively formed, elongated and broken, and the products, such as nitrous oxide, are removed by cooling to the liquid or solid state.—O. F. H.

Carbides [of calcium, etc.]; Process of smelting metallic compounds and producing —. E. F. Price, Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 904,991, Nov. 24, 1908.

A CALCIUM compound reducible by carbon is directly heated by allowing it to fall through a heated atmosphere. The heat unabsorbed in this process is used to "indirectly" heat carbon. The two materials are then mixed and further heated electrically.—A. G. L.

Electrode. A. G. Davis, Schenectady, N.Y., Assignor to General Electric Co., New York. U.S. Pat. 905,666, Dec. 1, 1908.

IN the electrical treatment of gases, electrodes composed of iron chemically combined with another element, e.g., magnetic oxide of iron, are used for the production of long arcs.—F. R.

Galvanic element. C. F. G. A. Heil. Fr. Pat. 392,429, July 1, 1908. Under Int. Conv., April 10, 1908.

THE claims are for a depolariser consisting of mercury sulphate, mixed with a convenient proportion of graphite and mercury oxide, and an electrolyte consisting of a solution of magnesium and potassium sulphates.—O. F. H.

Electrolyte for a depolarising galvanic element containing compounds of mercury. C. F. G. A. Heil. Fr. Pat. 392,430, July 1, 1908. Under Int. Conv., June 12, 1908.

THE electrolyte consists of an aqueous solution of acetates of metals, particularly potassium acetate.—O. F. H.

Electric resistance furnace; High pressure —. J. Josselin. Fr. Pat. 392,465, July 18, 1908.

THE furnace, which is intended to be used for the manufacture of diamond and for other purposes, consists of a strong, hollow steel cylinder and is heated by means of a carbon resistance of convenient form placed between the electrodes. Tin solder is used as a seal for the cover and for the electrode carrier, both of which are water-cooled. A pump is used for forcing gases under great pressures into the interior of the furnace.—O. F. H.

Nitrogen oxides; Production of — [from air]. F. Haber and A. Koenig. Fr. Pat. 392,670, July 13, 1908. Under Int. Conv., July 24, 1907.

OXIDES of nitrogen are produced by passing air, under reduced pressure, through a narrow cylindrical vessel in which an electric arc is maintained in such a manner that it fills or nearly fills the vessel. An excessively high temperature is avoided by having the walls of the vessel suitably cooled. Gas containing 9.5 to 10 per cent. of oxides of nitrogen is stated to be easily obtained.—F. R.

Electric furnaces. H. Nathusius, and Westdents, Thomas-phosphatwerke, Berlin. Eng. Pat. 7923, April 9, 1908. Addition to Eng. Pat. 7188, April 1, 1908.

SEE Addition of March 30, 1908, to Fr. Pat. 388,668 of 1907; this J., 1908, 1026.—T. F. B.

Compounds of oxygen and nitrogen; Production of —. F. Haber and A. Koenig, Karlsruhe, Germany. Eng. Pat. 15,490, July 21, 1908. Under Int. Conv., July 24, 1907.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Ergot oil, lycopodium oil, and arcea nut fat; Characteristics of —. A. Rathje. Arch. Pharm., 1908, 246, 692-706.

Ergot oil, obtained from *Scelus cornutum*, is a dark brown oil which thickens a little on cooling. It has a somewhat pungent taste and a not very characteristic odour. The following values were obtained with three samples:—Sp. gr. (one sample), 0.9250; refractometer reading (one sample), 1.4685; acid value, 11.31, 11.46; saponification value, 178.4 to 180.2; iodine value, 73.4 to 74.5; Helmer value, 95.84 to 96.6; Reichert-Meissl value, 0.61 to 0.67; acetyl value, 27.43 to 31.38; unsaponifiable matter (one sample), 0.36; mineral matter, 0.2 per cent.; and alkaloids, 0.6 per cent. *Fatty acids* (average of two samples), neutralisation value, 183.0; mean molecular weight, 307; iodine value, 77.2; and m. pt. (one sample) 38°-39° C. The fatty acids, it was concluded, comprised 68 per cent. of oleic acid, 22 per cent. of hydroxyoleic acid, and 5 per cent. of palmitic acid.

Lycopodium oil is a bright yellowish-green oil, which may be obtained by extracting the spores of lycopodium with chloroform. A yield of 49.2 per cent. was thus obtained of a product which gave the following values:—Sp. gr., 0.93617; refractometer reading, 1.4671; acid value, 18.6; saponification value, 195.0; iodine value, 81.0; Helmer value, 88.0; Reichert-Meissl value, 7.3; acetyl value, 53.8; (true acetyl value, 44.1); glycerol, 7.8 per cent.; unsaponifiable matter, 0.43 per cent.; and mineral matter, 0.03 per cent. *Fatty acids*, m. pt., 39°-40° C.; neutralisation value, 202.0; mean molecular weight, 278.0; and iodine value, 91.8. The fatty acids were found to have the following composition calculated upon the oil:—Lycopodium acid (dihydroxystearic acid) 3.2; lycopodic acid, 81.0; stearic acid, 1.13; palmitic acid, 0.85; and myristic acid, 2.0 per cent. The lycopodic acid separated by treatment of the lead salts of the fatty acids with benzol was a yellow liquid with an iodine value of 98.7,

and a molecular equivalent of 256.8 (theory for an acid of formula, $C_{16}H_{30}O_2=254$).

Arcea nut fat:—The substance obtained by extracting the nut with ether was a reddish-brown fat with an odour recalling that of nutmeg, whereas that obtained by extraction with petroleum spirit was yellowish-white and nearly odourless. Both fats were solid at the ordinary temperature. On analysis they gave the following results:—

Both fats contained about 5 per cent. of glycerol, 1 per cent. of unsaponifiable matter, and 0.02 to 0.03 per cent. of mineral matter. The fatty acids had the following composition respectively:—Stearic acid, 2.25 and 3.3; palmitic acid, 3.1 and 2.47; myristic acid, 21.0 and 24.7; lauric acid, 43.65 and 53.3; capric acid, 1.0; and oleic acid, 29.0 and 14.5 per cent.—C. A. M.

Japanese fish oil; Solid constituents of —. H. Okada. Chem.-Zeit., 1908, 32, 1199-1201.

THE oil examined was derived from various species of herring. It was completely soluble in 30 times its volume of a mixture of 40 parts of ether and 60 parts of alcohol. On adding to 100 c.c. of this solution the same volume of 95 per cent. alcohol, and cooling the liquid to -10° C., a white flocculent precipitate (m. pt. 30°-33° C.) was obtained, and from this was finally isolated by successive treatments with the mixture of ether and alcohol, an apparently homogeneous substance melting at 34° to 35° C. This had a saponification value of 195.9; an iodine value of 29.7; and a refractometer reading of 1.4545 at 41°-42° C. The liberated fatty acids were fractionated by the lead-ether method, and found to contain oleic acid and solid fatty acids, which from the results of fractional precipitation corresponded to a mixture of stearic and isocetic acids. The solid substance isolated from the oil thus corresponded to a mixed glyceride with the formula,

which has a theoretical iodine value of 29.5 and saponification value of 195.2.—C. A. M.

Waxes of the Coniferae; a new group of natural compounds.
J. Bougault and L. Bourdier. Compt. rend., 1908, 147, 1311-1314.

THE authors have isolated from the leaves of several species of Coniferae (juniper, pine, thuja, etc.), a series of crystalline waxes constituting a hitherto unrecognised group of chemical substances. The isolation of these waxes was based on their solubility in hot, and insolubility in cold 90 per cent. alcohol; their purification which is effected by various organic solvents is a very laborious process. The wax of *Juniperus sabina*, m. pt. 73°-78° C., was resolved into fractions melting at 68°, 72°, 76° and 82° C., which are not necessarily single substances but are all of the same type. All these bodies are of acid character; when the acid is neutralised by alcoholic potash, they are soluble in hot water, but the solution forms a soap-like jelly on cooling. The waxes also possess a free alcoholic group capable of acetylation. They are also esters, having a saponification value of about 230, but the whole of the products of hydrolysis are acids, no purely alcoholic compounds, such as glycerol, etc., being formed. When the alcoholic solution of the saponified wax is neutralised and treated with barium chloride, the whole of the organic matter is precipitated as barium derivatives insoluble in benzene or

cold ether. Consequently the waxes are esters of alcoholic acids, in which the carboxyl group of one molecule is esterified with the alcoholic hydroxyl of another molecule of the same or a similar acid. In this way complex chains are formed, similar to the polypeptide chains studied by Fischer; the authors propose the name of *etholides* for these new waxes. It is probable that the number of simple hydroxy-acids taking part in the synthesis of the various etholides is not very large, and that the different etholides differ mainly in respect of the number of associated molecules and their order in the chains. The authors have isolated two of these component hydroxy-acids:—a *hydroxypalmitic acid*, m. pt. 95° C., present in all these waxes, which they call *juniperic acid*, and a hydroxylauric acid, called *sabianic acid*, m. pt. 82° C., found so far only in the fraction of the wax of *J. sabina* melting at 82° C.—J. F. B.

Soap; Hydrolysis of —, F. W. F. Ross, Chem. Trade J., 1908, 43, 540–541.

THE author states that the effect of hydrolysis has received scant attention in attempts to determine the value of toilet soaps with respect to their action on the skin. It is stated that the liability to and rate of hydrolysis of a given soap does not depend upon the percentage of combined alkali, the proportion of water in the solid soap, or whether the soap is super-fatted or not, but is governed by the nature of the fats used in its preparation. Tests for toilet soaps are described based on the use of a 1 per cent. solution of phenolphthalein in absolute alcohol. Comparative tests are made on the soap under examination and a neutral standard soap, and the results are given in terms of the time required to obtain a pink colour with the phenolphthalein solution diluted with a known quantity of water, or the relative amounts of water which have to be added to the phenolphthalein solution in order to obtain, in the same time, tints of the same depth on the standard soap and on the soap under examination. —A. S.

Lavender oil; Adulteration of — with the esters of fatty acids of coconut oil, T. Delphin, See XX.

PATENTS.

Cod-liver oil emulsion; Apparatus for the manufacture of —, S. A. Sheard, Leeds, Eng. Pat. 492, Jan. 8, 1908.

THE apparatus consists of a hollow drum mounted horizontally in adjustable bearings, and within which, on a central shaft, are mounted a number of perforated blades. The drum and the blades are capable of being rotated in opposite directions. The oil and flavouring essences are run continuously into the drum, which is also charged continuously, through the hollow end of the central shaft, with the requisite amount of "mucilage" or like material, from reservoirs mounted above the drum, means being provided for regulating and checking the feeding of the different materials. —E. W. L.

Oil; Apparatus for decolorising, bleaching, and thickening —, See Noury et Van Der Lande, Fr. Pat. 392,793, July 30, 1908.

THE patent relates to the process of decolorising, bleaching, and thickening oils by subjecting them to the action of heat and of air under pressure in an apparatus provided with an agitator. The apparatus consists of a jacketed cylindrical vessel, divided by transverse partitions into compartments, which communicate with one another alternately at the centre and at the circumference. Alternate partitions are fixed to a central shaft and rotate with it. On the upper and lower sides of the partitions a series of projecting wings or blades, of trapezoidal shape, are mounted, whereby a thorough agitation and mixing of the oil and air are effected. —A. S.

Soap and process of making soap, C. Ellis, Larchmont, N.Y., Assignor to Ellis-Foster Co., N.J. U.S. Pat. 904,520, Nov. 24, 1908.

ABOUT 300 parts of commercial oleic acid are sprayed upon about 500 parts of a fixed alkali such as soda ash;

the mixture is then stirred and heated at a temperature of 250° F. until combination has taken place, when the resulting soap is cooled and ground. The mixing, stirring, and heating are carried out as a continuous process.

(A).—PIGMENTS, PAINTS.

Lead chromate ["chrome yellow"] and its change of colour, K. Jablczynski, Chem. Ind., 1908, 31, 731–733.

FRESHLY-PRECIPITATED lead chromate gradually changes in colour from light yellow to orange, and in practice a certain proportion of lead sulphate is precipitated with the chromate in order to prevent this change from taking place (see this J., 1891, 709; 1899, 843). The author has found that when lead chromate is precipitated in presence of excess of normal lead acetate, the yellow precipitate does not change in colour when left in contact with the solution, nor even when boiled with the latter, but if separated and washed with water or with acetic acid, it then gradually acquires an orange tint. If the precipitation be effected in presence of excess of basic lead acetate, the colour of the precipitate changes gradually (or immediately on boiling) from golden yellow to red; this change is attributed by the author to the separation of water from the basic lead chromate, $Pb_2(OH)_2CrO_4$, first precipitated, with formation of the compound, $O \left\langle \begin{smallmatrix} Pb \\ Pb \end{smallmatrix} \right\rangle CrO_4$ ("chrome red," Chinese or Persian red).

THE prevention of the change of colour of normal lead chromate ("chrome yellow") in the experiments described above was evidently due to the presence of excess of lead acetate. Further experiments showed that the change is also prevented by as little as 10 per cent. of lead sulphate; barium sulphate and lead phosphate do not prevent the change; lead oxalate causes reduction of the "chrome yellow." According to the author the change of colour is due to the hydrolysis of the lead chromate, which is not completely insoluble in water. The dissolved portion yields in solution lead ions and chromate ions: $PbCrO_4 \rightleftharpoons Pb^{++} + CrO_4^{--}$. By the union of the lead ions and the hydroxyl ions of the water, the basic ions, $PbOH^+$, are formed, and these combine with chromate ions to produce basic lead chromate, $Pb_2(OH)_2CrO_4$ (the parent substance of "chrome red"). If a soluble lead salt be present, it yields lead ions in solution, and these diminish the degree of dissociation of the lead chromate and thus limit the reactions mentioned. Lead acetate, being easily soluble, can be washed out of the lead chromate precipitate, and the change of colour can then take place. Lead phosphate is practically insoluble and thus incapable of preventing the change. Lead sulphate is sufficiently soluble to prevent the change of colour, but not soluble enough to be removed by washing. —A. S.

PATENTS.

Pigments; Production of colouring matters suitable for —. Badische Anilin und Soda Fabrik. Fr. Pat. 392,859. July 31, 1908. Under Int. Conv., April 2, 1908.

INDANTHRENE BLUE and other similar dyestuffs are obtained in a state very suitable for their use as pigments by reducing them with carbohydrates in alkaline solution. Example: 1000 kilos. of Indanthrene Blue RS are mixed with 9000 litres of water, and a mixture of 900 kilos. of caustic soda (40° B.) and 500 kilos. of glucose added. The whole is boiled for $\frac{1}{2}$ –1 hour, filtered, and washed. If, before the filtration a little colouring matter has passed into solution, air is bubbled through to precipitate it.

Turpentine oil as a by-product in the manufacture of wood-pulp by the sulphate process. P. Klason. See XIX.

PATENTS.

Resins, wax, gums, fats, oils or similar substances; Treatment of — with chlorine. The Electrolytic Alkali Co., Ltd., Middlewich, Cheshire. C. C. Connor, Belfast, and J. W. Stubbs, Middlewich. Eng. Pat. 741, Jan. 13, 1908.

IN order to moderate the violence of the reaction between gaseous chlorine and the substances enumerated in the title, these substances are dissolved in carbon tetrachloride and the gas passed through the solution. The progress of the reaction is indicated by the rise of temperature, and the reaction is complete when the temperature begins to fall. When an oxidised product is desired, water is added to the solution before passing in chlorine. The free acid is finally neutralised with alkali and the carbon tetrachloride distilled off, the chlorinated or oxidised product remaining behind.—E. W. L.

Varnish and manufacture thereof. F. R. Suter, Assignor to New Process Varnish Co., New York. U.S. Pat. 905,384, Dec. 1, 1908.

MOLASSES is boiled until most of the water is expelled, and is then introduced, under pressure, into a mass of melted resin, below the surface of the latter. The mixture is agitated, and then "a distillate of asphalt diluted with a suitable vehicle" is added.—A. S.

Varnish and paint with a base composed of derivatives of pimaric acid; Manufacture of —. Darrasse Frères and L. Dupont. Fr. Pat. 392,668, July 11, 1908.

CRUDE resinous exudations containing pimaric acid are filter-pressed, and the resulting cake, which is said to consist of almost pure pimaric acid, is dissolved in alkali. From the solution, metallic pimarates are obtained by precipitation with soluble salts of the respective metals. These metallic pimarates are dissolved in suitable solvents and utilised as substitutes for resins in the production of varnish and paints.—A. S.

(C.)—INDIA-RUBBER, &c.

Rubber from Manihot Glaziovii, and cultivation of the latter at Hawaii. Zimmermann. Der Pflanze, 1908, 4, 265; Gummi-Zeit., 1908, 23, 315.

THE tapping of the trees is effected by removing the hard layer of cork, and then making a series of vertical cuts; at the base the vertical cuts are connected by sloping ones. The duration of the flow of latex, usually from 2 to 5 minutes, may be increased by the usual "drip" method, the effect being greatest (30–40 minutes) when dilute (0.033 per cent.) ammonia is used. The collected latex is neutralised with dilute sulphuric acid, allowed to stand for half an hour, then mixed with a boiling concentrated solution of ammonium sulphate, heated up to, but not above 77° C., and allowed to stand. The rubber is removed from the surface, well washed, and kneaded to improve its mechanical properties; it is then dried either *in vacuo* or in a drying chamber, with or without simultaneous smoking. By tapping on the herring-bone system the yield obtained was poor, but it is believed that on the vertical system an annual yield of 2–4 kilos. per tree of 15 to 20 cm. diameter could be obtained. In January, 1908, there were about 360,000 *Manihot Glaziovii* trees and 20,000 *Hevea* and *Castillon* trees in Hawaii.—E. W. L.

Rubber latex; Studies on —. V. Henri. Caoutchouc et Gutta-Percha, 1908, 5, 2405. (See also this J., 1906, 940; 1907, 264.)

THE Brownian movement of the globules of *Hevea brasiliensis* latex has been followed cinematographically, and the effect of coagulating and other reagents upon it studied. The latex was diluted until only about 20 globules were visible in the field of the microscope, and the movement of each one of these could be accurately recorded, by taking photographs at intervals of 1/20th sec. with an exposure of 1/320th sec. The following displacements were found to occur in 1/20th sec. under the conditions named:—in the pure latex, 0.62 μ ; in presence of alkali, 0.31 μ ; in presence of acid, 0.07 μ . As the acidity increased, the globules could be seen to range themselves in chains, forming a network. The author again points to the distinction between "agglutination," as produced in *Hevea* latex by alkalis and salts of bivalent and trivalent metals, and "coagulation," as brought about by acids, alcohol, acetone, and certain salts. The former process is a reversible one, the latex being restored to its original condition by vigorous agitation, or by dilution with water; "coagulation" is not reversible.—E. W. L.

Rubber of Forsteronia floribunda from Jamaica. Bull. Imp. Inst., 1908, 6, 259–260.

A SAMPLE of the rubber of *Forsteronia floribunda*, a plant which is stated to grow profusely in the limestone district of Jamaica, was found to possess satisfactory physical properties; it had a strong odour of creosote. The rubber had the composition:—moisture, 10.8; caoutchouc, 79.3; resin, 6.3; protein, 1.4; insoluble matter, 2.2; ash, 1.26 per cent. It was valued at 2s. 4d. per lb., compared with fine hard Para rubber at 3s. 5d. per lb. —A. S.

Rubber cultivation in British Guiana. Board of Trade J., Dec. 24, 1908. [T.R.]

ACCORDING to the report on British Guiana for 1907–8, recently issued by the Colonial Office (Annual Reports, No. 589), 4000 acres of land on the banks of the Aruka and Kaituma rivers have been leased to a corporation for rubber cultivation, and further developments in this direction are pending. The output of balata for the year 1907–8 was 973,269 lb., as against 634,242 lb. in 1906. The quantity of rubber produced was also greater, 6873 lb. having been gathered as against 2563 lb. in the preceding year. The price of balata was fairly maintained, whilst that of rubber fell. Licences for the collection of balata were previously limited to three years, but in response to a general demand for a longer period they are now being issued for 15 years, and 164 more licences were taken out in 1907–8 than in the previous year.

PATENTS.

Rubber solution; Process for vulcanising — Degen and Kuth, Düren, Germany. Eng. Pat. 9956, May 7, 1908. Under Int. Conv., May 14, 1907.

A SOLUTION of vulcanised rubber is said to be obtained by mixing together solutions of rubber and of iodine in suitable solvents. For example, a solution of 0.4 gram. of iodine in 100 grms. of carbon tetrachloride is added in the cold to a solution of 4 grms. of Para rubber in 100 grms. of carbon tetrachloride. The solution loses its stickiness and viscosity on standing, and can be filtered and sterilised. This solution of vulcanised rubber is said to be very useful for surgical purposes for covering the surface of the skin.—E. W. L.

Elastic and plastic material; Manufacture of — Rütgerswerke-A.-G. Fr. Pat. 392,669, July 15, 1908.

IS the process of solidifying oils by means of air, oxygen, sulphur, or substances yielding oxygen or sulphur, claim is made for incorporating naphthalene with the mass just before the operation is finished.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tannic and gallic acids; The action of reducing agents on — W. M. Gardner and H. H. Hodgson. Chem. Soc. Proc., 1908, 24, 272—273.

THE object of the work was to devise a rapid and accurate method for the estimation of tannic and gallic acids, and it was thought that a quantitative yield of benzoic acid might be obtained on reduction. Among the reducing agents tried were: zinc, sodium, magnesium, aluminium, sodium hyposulphite, and hydriodic acid; experiments being made in most cases under acid, alkaline, and neutral conditions. The general results were that tannic and gallic acids are little affected by neutral or acid reducing agents, but that they react readily in alkaline solution. In no case, however, was a quantitative yield of benzoic acid obtained, and this was shown to be due to the slow destruction of benzoic acid by alkaline reducing agents.

Phenols; Action of iodine on — and a modified process for the determination of tannic acid. W. M. Gardner and H. H. Hodgson. Chem. Soc. Proc., 1908, 24, 273—274.

THE authors have shown (see preceding abstract) that tannic acid in alkaline solution rapidly reacts with reducing agents, and, based on this observation, a quick and accurate method for the estimation of tannic acid has been developed. The process is carried out as follows: To an aqueous solution of tannic acid, standard iodine solution is added in excess. Aqueous sodium hydroxide is then added drop by drop until the colour due to the iodine disappears, "after which concentrated hydrochloric acid is added in sufficient excess to precipitate the unabsorbed iodine," the amount of which is estimated by standard sodium thiosulphate. Two estimations are necessary in the case of commercial tannins. Firstly, that of the total iodine absorbed, and secondly, that of the iodine absorbed after removing the tannic acid from the solution by precipitation with gelatin; the difference giving the iodine absorbed by the tannic acid. Previous work by Messenger and Voitaum (this J., 1890, 1970), F. Musset (Chem. News, 1885, 51, 42), and A. Moulade (J. Pharm. Chim., 1905, 22, 153) on somewhat similar lines has been repeated, and it has been further shown that the process is available for the estimation of many phenols, for example, phenol, catechol, quinol, salicylic acid, pyrogallol, and gallic acid, in addition to tannic acid. With these substances, the amount of iodine absorbed is in direct ratio to the number of hydroxyl groups present, one hydroxyl group requiring one molecule of iodine; but with other phenols the reaction, although

quantitative, is empirical. The presence of other groups, such as NO_2 , NH_2 , OCH_3 , as well as the position of the hydroxyl groups in the benzene nucleus, was found to have a determining influence on the course of the reaction. Following Wijs's investigations on the action of Hübl's solution, the authors think that the active substance is the hypiodite formed, but they are further investigating this assumption.

XV.—MANURES, &c.

Artificial fertilisers in Russia. Board of Trade J., Dec. 31, 1908, [T.R.]

THE imports of artificial fertilisers into Russia have shown an upward tendency for several years, the figures for the last two years being 413,558 pounds and 509,622 pounds, respectively. They consisted chiefly of sodium nitrate, kainite, superphosphate, and Thomas phosphate. Of the total quantity imported in 1907, 84,283 pounds came from the United Kingdom, 99,204 pounds from Belgium, and 326,124 pounds from Germany. It was composed of 118,061 pounds of sodium nitrate, 177,391 pounds of kainite, 39,672 pounds of superphosphate, and 183,487 pounds of Thomas phosphate, the first three all from Germany and the last from the United Kingdom and Belgium. (1 pound = 36.112 lb.)

XVI.—SUGAR, STARCH, GUM, &c.

Beet; Optically active non-sugar substances of the — E. Herles. Z. Zuckerind. Böhmen, 1908, 33, 176—182.

DURING the present season the beetroots worked up in numerous factories have shown a considerable amount of the so-called "undetermined losses" in conjunction with an apparently richer sugar content of the roots, thus confirming the author's conclusion (this J., 1908, 1168) that there is frequently present in beetroots a dextro-rotatory non-sugar substance which is destroyed by the action of lime at a high temperature. Against the contention of Weissberg that the effect observed is due to a precipitation of sugar as calcium or lead saccharate, he replies that solutions of pure sucrose, treated under the same conditions as the juice, with lime and normal lead acetate, do not show any alteration of polarisation, and that a comparison of the direct polarisation with the sugar found by the Clerget inversion method indicates a difference of 0.30 per cent. of sugar between diffusion juice and second saturation juice. —L. J. DE W.

Reducing sugars; Precipitation of — with basic lead acetate. A. H. Bryan. Internat. Sugar J., 1908, 10, 602—605.

IN order to determine the effect of different precipitants on reducing sugars, solutions of dextrose and levulose were prepared, using 5 grms. of sugar and 1 gram. each of magnesium sulphate and ammonium tartrate. To 50 c.c. of the sugar solution the precipitant was added and the volume made up to 100 c.c. After filtering, the excess of lead was removed with potassium oxalate and the sugar determined by Allihn's method. Normal lead acetate removed practically no reducing sugar; basic lead acetate, however, whether in solution or dry, and basic lead nitrate solution removed very large quantities of both dextrose and levulose, the latter sugar always in much larger amounts. In view of the manifest error involved, the American Association of Official Agricultural Chemists (Bulletin 107, Revised, Bureau of Chemistry, U.S.A.) have discontinued the use of basic lead acetate, and at the present time only the normal lead acetate solution is used. The effect of different lead salts upon the polarisation of mixed solutions of sucrose, dextrose, and levulose in the presence of optically inactive compounds precipitable by lead also showed that reducing sugars were carried down with the precipitate.—L. J. DE W.

Molasses; Viscosity of cane sugar — H. C. Prinsen-Geerlings. Internat. Sugar J., 1908, 10, 584—592.

THE concentration and temperature are considered to be the principal factors governing the viscosity of the molasses

in a massecuite; the content of gum, the decomposition products of reducing sugar and other deposits, and the presence of fine grains of sugar being only of secondary importance. From a manufacturer's point of view the molasses should be as little viscous as possible, so that it may be easily separated from the crystals without much washing in the centrifugals, since the object aimed at is to obtain the maximum of sugar in the crystallised form. The molasses should therefore be made as liquid as possible compatible with the keeping of its minimum sugar content. This may be accomplished by taking care not to drive the concentration of the last massecuites too far, or, in case they have become too much concentrated, to dilute them with dilute molasses. A water content of last massecuites (boiled to grain), after the dilution, of 10 per cent. (equivalent to 96° Brix) and a water content of the molasses drained off from it of 20 per cent. (equivalent to 85° Brix) are the most favourable ones for the best desaccharification and the lowest viscosity. The cooling must not be pushed further than 45° C. and the temperature should remain preferably a couple of degrees over that figure. The increase of viscosity occasioned by the secondary factors enumerated above can be avoided by well conducted clarification, settling, filtering, boiling, and cooling processes.—L. J. DE W.

PATENTS.

Diffusion process and installation avoiding mixture of the [sugar] juice extracted with the juice in circulation and the macerating juice. J. C. Grière. Fr. Pat. 392,323. July 15, 1908. Under Int. Conv., Oct. 3, 1907.

FIG. 1.

FIG. 2.

In this diffusion process a more concentrated and hotter juice than usual is drawn off, and macerating is commenced with a weaker juice, drawn from the second preceding diffuser, the temperature of the weak juice being regulated independently of the diffusion and of the circulation, so that an energetic exhaustion of the fresh chips is obtained, the duration of diffusion is shortened, and the battery may be made smaller. Water enters the upper part of diffuser, 1 (Fig. 1), by the water main, *w*, and valve, *a*₁; the juice leaves at the lower part of this diffuser, passes through *b*₁, into diffuser, 2, and thence by the valve, *b*₂, into diffuser, 3, then through *c*₃ into the juice main, *s*, and through valve, 7, into the measuring tank, *m*. This concentrated juice is subsequently drawn off. Meantime the chips are heated in diffuser, 4, by the circulation of juice, the juice passing from the lower part of the diffuser through the valve, *f*₄, and main, *x*, into the overflow receiver, *g*, from which it passes to the pump, *p*, which forces it through the heater, *e*, the main, *y*, and

valve, *e*₁, into the upper part of diffuser, 4. The macerating of the fresh chips has been simultaneously commenced in diffuser, 5. The weak juice in receiver, *m*₁, obtained from a previous operation in diffuser, 2, passes through the temperature regulator, *r*₁, the main, *M*, and valve, *d*₅, enters the lower part of diffuser, 5, and rises in it. By the interposition of the temperature regulator it is possible to effect macerating at any desired temperature independently of the temperature of the juice of the battery, as the juice passing through may be heated by steam or cooled by diffusion water or cold circulation juice. As soon as the necessary quantity of juice is collected in the measuring tank, *m*, the valve, 7, is closed and 9 opened, and the weaker juice is collected in the macerating-juice tank, *m*₂, ready for the macerating operation in diffuser, 6. The receivers, *m*₁ and *m*₂, are used alternately, in order to regulate more conveniently the duration of macerating and of the circulation of the juice. The overflow tank, *g*, (Fig. 2), which is open to the atmosphere, has a pipe, *i*, fitted inside, rising to a certain height in *g*, and connected with the main, *x*. This pipe serves to secure a definite and constant column of juice, thus producing a counter pressure in the diffuser in circulation and preventing any irregular packing together of the chips. The quantity of juice in circulation as well as the height of the juice in the receiver, *g*, are immaterial in this respect. The main, *n*, which leads from the bottom of the receiver to the pump, *p*, is connected inside *g* to a perforated pipe, *k*, to separate any pulp present in the juice. The pulp is run off occasionally by the main, *l*, into one of the diffusers. The receiver, *g*, is in communication with the macerating-juice receivers by the main, 10, which is closed by the float-valve, 11. When the level falls to the float, 11, juice passes from the receiver, *m*₁, into *g*. This happens when, owing to the output of the pump, the same quantity is not sent to the receiver, when the pulp is emptied from *g*, or when a heater is emptied. The pipe, 12, serves to run off juice into *m*₁, or *m*₂, when the level rises too high in *g*. In order to further prevent any chance of the receiver, *g*, overflowing, the float-valve, 13, is interposed in the main leading from the pump to the heater. This valve is connected to the float, 14, which closes the valve and stops the circulation when the level rises too high. To prevent air from entering the pipe, *n*, which might occur on commencing operations, the float-valve, 15, is arranged to stop the circulation when the level falls too far. The receiver, *g*, is only of small dimensions since it serves principally to secure a column of juice of uniform height to give a counter-pressure in the diffuser.

—L. J. DE W.

Sugar; Apparatus for the manufacture of —. Raffinerie Moderne (Procédé Natta). Fr. Pat. 392,540, July 22, 1908.

The vacuum pan contains a central, vertical, rotary shaft around which are arranged, one above the other, a number of circular hollow shelves heated internally by a main steam conduit. Two types of shelves are placed alternately, one type fitting close to the shell at its outer periphery and leaving an annular space around the central shaft, and the other type fitting close to the shaft and leaving an annular space around the outer periphery of the shelf. Thus the syrup, distributed on the top shelf by means of a perforated pipe, flows from one shelf to another in a radially zig-zag course towards the bottom of the pan. The rotary shaft carries scraper-arms which sweep the circular shelves and cause the transference of the grainy syrup from one shelf to the next. The massecuite collects below the system of shelves in the lower part of the pan and is kept in agitation by the shaft until the boiling is finished.—J. F. B.

Green refinery syrups; Apparatus for concentrating and boiling —. Raffinerie Moderne (Procédé Natta). Fr. Pat. 392,541, July 22, 1908.

The steam evolved from the boiling of juices and syrups is conducted into the steam chamber of a concentrating apparatus constructed on the same principle as that described in Fr. Pat. 392,539 (see above), and is thus

caused to heat the interior of two alternate series of hollow shelves over which a cascade of the refinery syrup is allowed to run.—J. F. B.

Sugar juices and refinery syrups; Apparatus for concentration of — in vacuo. Raffinerie Moderne (Procédé Natta). Fr. Pat. 392,539, July 22, 1908.

The apparatus consists of a rectangular shell with a domed top connected with a vacuum pump. Inside, arranged in duplicate series (one shown in fig.), are: a central divided steam conduit, B, and side steam conduits, K and L. Connected with the side and central conduits, alternately, are a number of hollow shelves, D, F, heated internally, and arranged one above the other at a slight incline, so that juice entering at U, U', will fall from shelf to shelf, boiling under the action of the vacuum and becoming progressively concentrated until it reaches the bottom. The juice is kept on the shelves, in layers not exceeding 1 cm. deep, by slightly raised border-strips, d. The doors, V, V', V'', give access to all parts of the apparatus. In order to prevent caramelisation, hydrosulphite, glycerol, or "oil" may be injected

tion, hydrosulphite, glycerol, or "oil" may be injected to the lower shelves.—J. F. B.

Carbohydrates soluble; Process for rendering —. A. Boidin, Seclin, France, Assignor to Soc. Anon. Anwerp, Antwerp, Belgium. U.S. Pat. 906,188, Dec. 8, 1908. SEE Fr. Pat. 335,366 of 1903; this J., 1904, 197.—T. F. B.

Dryer; Mechanical rotary or revolving — for removing water from mequass, etc. Eng. Pat. 25,131. See I.

XVII.—BREWING, WINES, SPIRITS, &c.

Malt extract; Increase in the yield of — by previous doughing-in of the grist. C. Bleisch. Z. ges. Brauw., 1908, 31, 633—636.

IN Bavaria it was formerly very common to allow the malt grist to lie in dough for some time before the mashing proper was proceeded with, but no numerical expression of the benefit thereby produced in the yield of extract was to be found till recent work of van Hest showed that an increase of at least 2 per cent. was obtained. The subject has been investigated at Weihenstephan, where malts have been mashed on this principle and the yield of extract compared with that obtained in the ordinary way. In laboratory experiments the finely ground malt was doughed-in at 50° F. and allowed to stand 14 hours at the ordinary temperature, after which it was mashed in the customary way. In nine experiments the yield was increased from 0.47 to 1.79 per cent., with an average of 1.3 per cent. On the large scale such comparative mashes are difficult to obtain owing to the difficulty of securing exactly similar grists and extractions

of the goods. Finally three duplicate mashes were secured and in them the yield was increased by 1.85, 0.57, and 1.35 per cent. respectively by the previous doughing-in of the malt. The author has always considered that loss of extract can only be due to unconverted starch left in the grains, or to soluble matter not properly washed out of them. The unconverted matter in the grains usually varies from 0.3 to 0.8 per cent. of the malt and cannot reach the value, 2.0 per cent., given by van Hest for the increase to be obtained. The grains from the large-scale mashes were therefore examined and it was found that a gain of only 0.2 per cent. could be accounted for by increased conversion. The soluble protein and ash were then estimated in comparative mashes and in each case were found to be increased by the doughing-in operation. The author concludes that the increase in extract obtainable by the modified mashing process is illusory and only in small part due to better extraction of the goods, but is chiefly to be referred to increased solution of protein and ash, together with, possibly, an altered saccharification of the starch.—R. L. S.

Yeast cell-juice; Action of colloidal ferric hydroxide on —. F. Resenschek. Biochem. Zeits., 1908, 15, 1—11.

It has been observed that when yeast cell-juice is subjected to the action of an electric current, the liquid around the cathode acquires a stronger fermentative power than the liquid near the anode. This suggests that the fermentative enzyme is a colloid which should be precipitated by colloids of opposite function, e.g., ferric hydroxide. When a dialysed sol of ferric hydroxide, containing 26 grms. of the hydroxide per litre, was mixed with an equal volume of cell-juice, a red-brown flocculent precipitate was formed containing the whole of the iron together with some of the proteins of the juice. This precipitate was separated by means of the centrifuge, and was examined comparatively with the juice from which it had been obtained. The precipitate itself was devoid of fermentative power, but possessed stimulating properties identical with those of the co-ferment discovered by Harden and Young (this J., 1906, 490, 1111); it likewise contained phosphoric acid. The juice from which the precipitate had been removed, when compared with some original juice, showed a decreased fermentative power, corresponding with the removal of some of its co-enzyme, but in the course of 3—4 days' fermentation, it was capable of recuperating this loss, and the final fermentative result was practically the same. When the precipitate produced by acetone in the treated juice was compared with the acetone precipitate from the original juice, the loss of fermentative power was permanent and no recuperation took place. The ferric hydroxide precipitate and the co-enzyme precipitated from boiled cell-juice were proved to be reciprocally interchangeable and their identity is established. The co-enzyme does not exist in the precipitate in combination as ferric phosphate, nor is it merely carried down mechanically, since it cannot be removed from the precipitate by thorough washing; probably the two colloids form an adsorption compound of an intermediate degree of stability.—J. F. B.

Alcoholic fermentation; Influence of stannous chloride and other mineral salts on —. G. Gimel. Compt. rend., 1908, 147, 1324—1326.

IT is known that, in addition to the recognised nutrient elements, there are certain special mineral salts, the presence of which in traces may exert a favourable influence on the growth of micro-organisms. For instance in Raulin's culture medium, the addition of traces of zinc salts stimulates the growth of *Aspergillus niger*. Similarly Kayser and Marchand found that the presence of 5—10 parts of manganese sulphate per 10,000 parts of liquid had a favourable effect on alcoholic fermentation. The author has now studied the effect of a large number of metallic salts on cultures of yeast; two of the salts, viz.: bismuth subnitrate and stannous chloride gave positive results. The addition of 1 part of stannous chloride per 10,000 of must, was found to increase the yield of alcohol by about 4 per cent., whereas 10 times that quantity of manganese sulphate only increased the yield by 2—3.

per cent. Stannous chloride accelerates the revivification of the yeast which is sown in the must, and cultures taken from the yeast so produced retain a similar property for a certain length of time. Stannous chloride also has a partial decolorising action on the must, particularly in the case of molasses, which appears to be favourable to the development and activity of the yeast.—J. F. B.

Molasses rum in Japan. K. Saito. Cent. Bakt., 1908, 675; Z. Spiritusind., 1908, 31, 565.

THE inhabitants of the Japanese island of Bonin prepare an alcoholic drink by the spontaneous fermentation of sugar-cane molasses, at a moderate dilution, in casks in a warm room. Fermentation sets in after a few days, with the formation of a white frothy "head," and the liquor is finally distilled. The spirit is a colourless rum with a slightly acid flavour. Analysis showed: sp. gr., 0.9543; alcohol, 38.54 per cent. by volume; acid (as acetic acid), 0.174 per cent. Acetic acid and furfural were present, as well as traces of fusel oil. From the molasses wash, the author isolated a species of yeast, which when grown in "koji" decoction or molasses wort, forms a delicate white film which readily falls to the bottom. The yeast occurs as roundish or oval cells of 6–10 μ diameter; these form at temperatures of 18°–30° C. 1–4 spores, which multiply by budding. This yeast is probably *Pichia californica*; it produces no fermentation in beer wort; it does not ferment sucrose, but only dextrose and laevulose; a vigorous surface growth, however, occurs on sucrose media. It produces 4.8 per cent. of alcohol in "koji" decoction, but only 2.4 per cent. in molasses wort, since it ferments only the monose sugars present; it is capable of growth in presence of 20 per cent. (by volume) of alcohol in "koji" decoction containing 50 per cent. of dextrose.—J. F. B.

Guaiacum reaction; Contribution to the knowledge of the —. C. L. Alsberg. See XXIII.

Denatured alcohol; Formula for making chloral hydrate in the United States. Oil, Paint, and Drug Rep., Dec. 7, 1908. [T.R.]

THE U.S. Commissioner of Internal Revenue has approved the following formula for specially denatured alcohol to be used in the manufacture of chloral hydrate:—

Formula 17.—To 100 gallons of ethyl alcohol add 0.05 gallon (6½ fluid ounces) of animal oil.

The animal oil must conform to the following specifications:—

The colour shall be a deep brown.

Boiling point.—When 100 c.c. of the animal oil are subjected to distillation in the same manner as prescribed for the determination of wood alcohol in Section 26, Part I, of the regulations, not more than 5 c.c. should distil over below 90° C., and not less than 50 c.c. at 180° C.

Pyrrol reaction.—2.5 c.c. of a 1 per cent. solution of the animal oil in 90 per cent. alcohol are diluted to 100 c.c. with alcohol. A splinter of pine wood, previously moistened with concentrated hydrochloric acid, is dipped into 10 c.c. of this solution, containing 0.025 per cent. of animal oil. After a few minutes the splinter should show a distinct red coloration.

Reaction with mercuric chloride.—5 c.c. of the 1 per cent. solution of the animal oil in 90 per cent. alcohol, when treated with 5 c.c. of a 2 per cent. solution of mercuric chloride in alcohol, should give immediately a voluminous flocculent precipitate. Five c.c. of the 0.025 solution of the animal oil, when treated with 5 c.c. of the 2 per cent. solution of mercuric chloride, should show at once a distinct turbidity.

PATENTS.

Malt; Preparation of a product capable of being preserved in good condition from green —. A. Weickmann. Ger. Pat. 203,944, June 26, 1906.

FINELY-DIVIDED green malt is mixed to a dough-like mass with a solution prepared from vegetable or animal

substances and containing mineral salts. The solution may be prepared by dissolving peptones, amides, etc., in a 2–6 per cent. solution of an alkali phosphate, nitrate, or sulphate, until the liquid has a density of 10°–30° Balling. It is stated that by this process the enzymic activity of the malt is not injured, and that the product can be preserved for months without suffering any depreciation in value.—A. S.

Ammonia and volatile fatty acids: Process of fermentation to obtain — from organic nitrogenous substances. J. Effront. Brussels. Eng. Pat. 9951, May 7, 1908. (Compare this J., 1908, 241, 953.)

THIS process of obtaining ammonia and volatile fatty acids, particularly from distiller's and yeast wastes, wastes from the manufacture of sugar, foul waters from wool scouring operations, or turf containing large proportions of nitrogen, consists in decomposing these materials by fermentation produced by yeast or moulds. Under this treatment, glycocoll is resolved into ammonia and acetic acid, and aspartic acid into ammonia and propionic acid. These fermentative decompositions are favoured by maintaining the fermenting liquid alkaline to an extent corresponding with 2.5–4 grms. of potassium carbonate per litre, by the presence of 30–50 grms. of aluminium sulphate or of a corresponding amount of other aluminium salt per hectolitre, or of calcium superphosphate.—T. H. P.

Beverages: Process of making fermented —. M. Wallerstein. New York. U.S. Pat. 905,029, Nov. 24, 1908.

A "RAW mash" is treated with malt at a temperature of 60°–65° C., in the presence of an excess of dissolved calcium sulphate. The conversion of the starchy constituents is then completed at a temperature above 74° C., and the product is diluted by the addition of malt mash to reduce the quantity of calcium sulphate to the desired proportion.—W. P. S.

Peat; Treatment of — for the production of alcohol. Sec. anon. Origo. Ger. Pat. 204,058, March 27, 1907.

THE essential feature of the invention consists in heating the peat at a high temperature, in an autoclave, with the acid fermented liquor from a previous operation. In starting the process, 400 kilos. of dry peat are treated with a mixture of 22 hectolitres of water and 24 kilos. of sulphuric acid of 53° B. Steam is forced in at the bottom of the autoclave and a pressure of 3 atmospheres is maintained for about 40 mins. The mass is then removed from the autoclave, treated with calcium carbonate, and cooled to 35° C. the neutralised mixture should contain about 3 grms. of free acid per litre. It is fermented by means of yeasts obtained from berries growing on peat moors. In succeeding operations, the sulphuric acid is replaced by an equal quantity of the acid fermented liquor. In the treatment in the autoclave it is necessary to open a cock to allow the air to escape, and this air, carrying with it steam, alcohol vapour, and volatile aromatic substances, is led to a condenser or dephlegmating column.—A. S.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, AND DISINFECTANTS.

(1.)—FOODS.

Phosphorus; Quantity and distribution of — in some foodstuffs. W. Heubner and M. Reeb. Arch. exp. Pathol. u. Pharmak., 1908, Supplementband. Schmiedeberg-Festschrift, 265–272. Chem. Zentr., 1908, 2, 1918.

THE amount of dry substance in the different materials was determined by first drying at 85° C., then finely powdering, and afterwards drying *in vacuo* over sulphuric acid. In a portion of the dry substance the total

phosphorus was determined by Neumann's alkalimetric method (Z. physiol. Chem., 37, 115) as modified by Von Wendt (Skand. Arch. Physiol., 17, 211) and Gregersen (Z. physiol. Chem., 53, 453). Another portion was extracted with 95 per cent. alcohol, the alcohol distilled off from the extract, and the phosphorus in the residue determined, i.e., the portion present as leathin-like compounds. The residue left after extraction with alcohol was dried, weighed, boiled with water, filtered, washed, and the phosphorus (as nuclein substances or phosphor-protein) determined in the dried residue. The phosphorus present as phosphate in the aqueous solution was precipitated with magnesia mixture, and after filtering, the phosphorus present as soluble esters (chiefly phytin, inositol-phosphoric acid) was determined. The results obtained are shown in the following table:

	Percentage of dry substance.	Percentage of phosphorus in the dry substance.					
		Total.		As phosphatide.	As soluble phosphate.	As soluble ester.	As nuclein and phosphor-protein.

Milk intended for analysis; Disadvantages of potassium bichromate as a preservative for —. A. Monvoisin. Compt. rend., 1908, 147, 1403—1404.

ACCORDING to the French law of Aug. 1, 1905, potassium bichromate is added (0.25 gm. per 250 c.c.) as a preservative to samples of milk taken for analysis. Grélot (J. Pharm. Chim., 1907) has already shown that such addition interferes with the determination of the acidity, cryoscopic point, and refractive index of the milk, and probably also with the detection of formaldehyde. The author has found that Storch's test with *p*-phenylenediamine for the detection of hydrogen peroxide and for distinguishing whether a milk has been heated or not, is also rendered useless by the addition of potassium bichromate, since in presence of this salt, pure fresh milk gives a blue coloration with *p*-phenylenediamine. (See also this J., 1908, 242).—A. S.

Dutch lard. C. Arragon. Chem.-Zeit., 1908, 32, 1227.

THE author draws attention to the presence on the market of Dutch lards which on examination give figures similar to those yielded by lard adulterated with beef tallow. These lards are prepared by pressing, with the aid of moderate heat, a portion of the so-called lard oil being thereby separated from the fat. Four samples gave the following figures:—Sp. gr. at 100° C., 0.8575—0.8588; refractometer reading at 40° C., 47.5—48.7; iodine value, 48.9—54.3; saponification value, 194.5—195.5. In view of these results the author emphasises the necessity of supplementing the usual methods of analysis by the microscopic examination of crystals of the fat, which is capable of detecting the presence of 10 per cent. of beef fat in lard.—A. S.

Caffeine; A source of error in the determination of — by Juckenack and Hilger's method. K. Lendrich and R. Mordfield. Z. Untersuch. Nahr. Genussm., 1908, 16, 647—658.

EXPERIMENTS to determine the cause of the low yields of caffeine obtained by the method of Juckenack and Hilger (this J., 1897, 567) showed that if the coffee was

completely dry, repeated extraction did not remove the whole of the alkaloid. In the authors' opinion this is to be attributed to adsorption of the caffeine by the divided material, and to the adsorption compound being only broken up with difficulty by chloroform or carbon tetrachloride when the substance is completely dry. To obviate this error, the filtered decoction treated as in Juckenack and Hilger's method is evaporated with sand or fragments of filter paper of about the same size, and the dry residue rendered moist by exposure in a vessel containing steam, and repeatedly extracted with carbon tetrachloride. The method may also be used for the determination of caffeine in roasted coffee, but it is necessary to calculate the proportion of alkaloid from a determination of the nitrogen in the impure residue obtained.—C. A. M.

PATENTS.

Milk; Process and apparatus for keeping — sound. T. G. Mollinger and A. Rompies, Nieuwer Amstel, Holland. Eng. Pat. 25,393, Nov. 15, 1907.

THE milk is first heated in a closed vessel to a temperature of 75° C., and is then pumped through a coil surrounded by a steam-jacket, by which it is heated to a temperature of from 150° to 160° C. It is next cooled to 90°—100° C., and delivered at this temperature, from a collecting tank into bottles or other receptacles. The bottles while being filled are arranged under a hood, and the necks are pressed against the end of the pipe discharging the milk. Caps placed over the necks of the bottles hermetically close the latter while the contents are still at a temperature near 100° C.—W. P. S.

Fruit juices and extracts; Preparation of concentrated —. O. Volz. Ger. Pat. 204,603, April 12, 1907. Addition to Ger. Pat. 184,760.

THE extract is freed from aromatic substances by the process described in the main patent, then concentrated, freed from pectin substances by treatment with several successive quantities of alcohol, and finally after distilling off the alcohol, and again concentrating, re-united with the aromatic substances.—A. S.

Cascien; Preparation of —. E. Soncini, Assignor to Soc. di Esportazione Polenghi Lombardo, Milan, Italy. U.S. Pat. 905,943, Dec. 8, 1908.

SEE Fr. Pat. 375,123 of 1907; this J., 1907, 887.—T. F. B.

(B).—SANITATION; WATER PURIFICATION.

PATENT.

Water; Method of purifying waste — [by electrolysis]. W. Rumin, Kharkoff, Russia. Eng. Pat. 25,222, Nov. 13, 1907.

THE water or effluent coming from septic tanks or biological filters is conducted to a tank in which electrodes are immersed; these electrodes have the form of a grating

or netting of porous material. On passing a current of electricity through the water, the substances in suspension are coagulated and precipitated on the bottom of the tank. (Reference is directed to Eng. Pats. 10,094 and 14,182 of 1903; 14,003 and 17,532 of 1904; 9002 and 25,940 of 1906; this J., 1903, 878, 1142; 1904, 947; 1906, 1114; 1907, 836.)—W. P. S.

(C).—DISINFECTANTS.

PATENT.

Insecticidal gas; Process of producing —. H. V. Walker, New York. U.S. Pat. 905,609, Dec. 1, 1908.

A MONOHYDROXY-DERIVATIVE of an aromatic hydrocarbon containing from six to ten atoms of carbon, and possessing insecticidal properties when in a state of vapour, is mixed with quicklime, and with a reagent which in solution has a greater affinity for lime than the hydroxy-derivative, and then water is added to combine with the quicklime. The proportions of quicklime and water are so adjusted that the heat evolved is sufficient to vaporise the hydroxy-derivative.—A. S.

XIX.—PAPER, PASTEBOARD, &c.

Sulphate cellulose mills; Volatile by-products of —. H. Bergström and O. Fagerlind. *Papier-Zeit.*, 1908, 33, 3779.

IN a wood-pulp mill working the sulphate process, with a maximum pressure in the digesters of 10 atmospheres, the following quantities of by-products were condensed from the vapours discharged from the digesters in the course of manufacture:—Oil of turpentine, 8 kilos. from pine wood, 1 kilo. from spruce wood; methyl alcohol, 5 kilos.; methylmercaptan, 1 kilo.; dimethyl sulphide, 3 kilos.; dimethyl disulphide, 0.1 kilo.; ammonia, 0.2 kilo., all quantities being calculated per ton of finished cellulose. The presence of hydrogen sulphide, carbon dioxide, and acetone was also observed, as well as that of two bodies, not isolated, to which the peculiar difficulty experienced in clarifying the oil of turpentine of this origin, is to be attributed. It should, however, be noted that the digester-gases are not the only source of nuisance in a sulphate pulp mill; equally noxious gases are discharged, in perhaps larger quantities, from the soda-recovery plant.—J. F. B.

Turpentine oil as a by-product in the manufacture of wood-pulp by the sulphate process. P. Klason. *Papier-Zeit.*, 1908, 33, 3779—3780.

THE quantity of turpentine oil obtained as a by-product in the manufacture of wood-pulp by the sulphate process is about 5 kilos. per ton of wood (*Pinus sylvestris*), but it is of low quality owing to the presence of noxious sulphur impurities. Comparatively few of the sulphate pulp mills recover this turpentine at the present time, but since one of the first steps towards the suppression of the nuisance caused by these mills, consists in condensing the volatile by-products (see this J., 1908, 1219) more attention will probably be paid to their utilisation. The fraction of the crude oil distilling below 100° C. consists chiefly of dimethyl sulphide; this may be freed from traces of mercaptan and trimethylamine by agitation with lead acetate. The fraction distilling between 100° and 150° C. contains dimethyl disulphide. This body does not exist originally in the vapours discharged from the digesters, but is produced by the oxidation of methylmercaptan under the peroxidising influence of the turpentine in presence of air. As a rule, these two fractions do not amount to more than 5 per cent. of the crude oil. The turpentine oil, when distilled in a current of steam, leaves a brownish residue of polyterpenes. The major portion of the purified oil, consisting mainly of pinene, distils between 155° and 158° C. and has a sp. gr. of 0.8601. In spite of the removal of the sulphides in the fractions of low

boiling point, the resulting oil of turpentine has an objectionable secondary odour, which cannot be removed by fractionation and which is particularly noticeable when the oil is used in paints. In some cases this odour may be eliminated by treating the oil with 4 per cent. of its weight of 50 per cent. sulphuric acid, but frequently this treatment fails. The sulphur compounds are more soluble in the turpentine than in the acid, so that a limit is soon reached in the efficacy of the treatment. If the oil contain only dimethyl sulphide it may be deodorised, but if dimethyl disulphide be present its odour cannot be eliminated completely. Dimethyl disulphide boils at 117° C., only about 40° C. lower than the oil of turpentine itself, so that its elimination by fractional distillation is difficult. Moreover, its odour is more disgusting, more permanent, and very much more poisonous than those of the ordinary sulphide and of the mercaptan. The solution of the difficulty lies in the fact that the disulphide is a secondary product of the oxidation of the mercaptan, and is not originally present in the oil. If, then, the purification of the turpentine oil be undertaken immediately after its production, the disulphide is not formed, and a finer quality of turpentine oil is obtained than when the crude oil has been stored for some time.—J. F. B.

Alkali-cellulose; The constitution of —. O. Miller. *Ber.*, 1908, 41, 4297—4304.

THE author criticises a paper by Vieweg on this subject (this J., 1908, 1081), in which he communicates some re-determinations, made by Haupt, of the absorption of sodium hydroxide from its solutions by cellulose, which he contends support his previous conclusion as to the existence of Gladstone's compound, $C_{12}H_{10}O_{10}Na$. Vieweg, the author states, has overlooked the fact that Haupt's numbers differ considerably from the relationships previously recorded (this J., 1907, 1157). The author has calculated these numbers so as to show that, except for very low and very high concentrations of sodium hydroxide, when secondary effects come into play, the ratio of the concentrations of the alkali in the solid and liquid phases respectively is approximately a constant. This fact supports the present author's view that alkali-cellulose is a solid solution. It would appear from Haupt's results that there is no horizontal portion in the absorption-concentration curve starting at 16 per cent. of sodium hydroxide, but that the curve rises steadily until a concentration of 20—24 per cent. is reached. At this point it falls somewhat, and this fall is due to decompositions which take place in the solid phase. These decompositions have been studied by the author, who has shown that they are dependent on the time of contact. With regard to the influence of sodium chloride on the distribution of the hydroxide between the two phases, it would appear that the molecular weight of the hydroxide in the cellulose is greater than in the aqueous chloride solution.—J. F. B.

Peat; Contribution to the study of the humic substances of —. L. Roger and E. Vulquin. *Compt. rend.*, 1908, 147, 1404—1406.

THE humic substances were obtained by treating fibres of peat wadding ("Fovate de tourbe") with a 10 per cent. solution of sodium hydroxide, precipitating the solution with hydrochloric acid, washing the precipitate free from hydrochloric acid, and drying on glass plates at a low temperature. Analysis showed that the conversion of vegetable matter into peat is accompanied by an accumulation of nitrogen and carbon in the product. The humic substances contain neither pentosans nor hexosans, but the alcoholic function of the celluloses from which they are derived is not destroyed, since an acetyl derivative (yielding 30 per cent. of acetic acid) and a derivative (containing 20 per cent. of sulphur) analogous to cellulose thiocarbonate, can be prepared. On fusion with alkali the humic substances yield protocatechuic acid, whilst on hydrolysis with alkali or sulphuric acid and on destructive distillation, they yield products containing acetic acid; they absorb halogens. They possess acid properties, combining with alkalis to form soluble products; they can also combine with a considerable quantity of ammonia; these acid properties are destroyed by oxidation.—A. S.

PATENTS.

Fibres for papermaking; Process for treatment [digestion] of —. Soc. Anon. des Papeteries de Galas. Fr. Pat. 392,486, July 20, 1908.

THE digestion of fibrous materials for conversion into paper pulp, which must be carried out under high pressure, is generally effected at a temperature corresponding with that of water boiling at that pressure. According to this invention, the injurious action of the chemicals at such high temperatures is avoided by creating the necessary pressure mechanically, whilst the temperature of the digesting liquor is not allowed to rise above 100° C. The apparatus consists of a rotary digester of the usual type, an external heating coil, and a pump in circuit with the coil and digester. The fresh-liquor cistern is connected with the circuit by a three-way cock. The digester is first charged with liquor, fresh liquor is then pumped from the cistern through the heating coil and into the digester until the desired pressure is attained. Finally digestion is continued under this pressure by pumping the liquor from the digester, through the coil, and back into the digester at a different point. The resulting fibres, after washing, may be partially bleached by acidifying with sulphuric acid.—J. F. B.

Paper; Manufacture of — impermeable to water and untearable. Soc. anon. des Papeteries de Galas. Fr. Pat. 392,489, July 20, 1908.

UNSIZE paper, prepared preferably of long fibres, is passed through a cold solution of caoutchouc or gutta-percha, and then dried in a stove in a current of hot air. Such paper is claimed to be impermeable to water and untearable and not to change in dimensions when wetted.—J. F. B.

Paper pulp; Economical production of —. C. Badoil. Fr. Pat. 392,750, July 27, 1908.

PLANTS such as the asphodel are boiled with water once or several times in succession, being pressed after each treatment, in order to recover such substances as glucose, gum, etc., and are then boiled under pressure with a small proportion of "soda."—A. S.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

Strychnine and brucine; Iodine derivatives of —. J. Buraczewski and T. Kozniowski. Anz. Akad. Wiss. Krakau, 1908, 644—649. Chem. Zentr., 1908, 2, 1872.

BY the action of a solution of iodine in carbon bisulphide on solutions of the alkaloids in hot 96 per cent. alcohol, almost quantitative yields of di-iodo-derivatives of strychnine and brucine were obtained. *Di-iodostrychnine* forms small scarlet crystals; it melts at 196—197° C., is almost insoluble in water, aqueous alkali and the usual organic solvents, and is not altered on heating to 165° C. *Di-iodobrucine* forms small silky crystals of a cinnamon-colour; it melts at 222.5° C., is somewhat hygroscopic, and has properties similar to those of the corresponding strychnine compound. Both compounds are decomposed by alcoholic alkali, with regeneration of the alkaloids. On prolonged boiling with alcohol, the compounds are partially decomposed, with separation of compounds containing larger proportions of iodine, that from the strychnine derivative melting at 253—254° C., and that from the brucine derivative at 251°—252° C.—A. S.

Hordenine sulphate; Therapeutic value of —. J. Sabrazès and G. Guérive. Compt. rend., 1908, 147, 1076—1079.

HORDENINE (this J., 1906, 133) is *p*-oxyphenylethyldimethylamine. The sulphate crystallises in needles and has a slightly bitter taste; its aqueous solution may be

sterilised at 120° C. It gives no precipitate with the tannins of vegetable infusions, and forms brown crystals in contact with iodine. One mgrm. per kilo. has a tonic action on the heart, but toxic doses (1—2 grms. per kilo.) produce the reverse effect by suspending the activity of the pneumogastric nerve. Although not acting with the energy of digitalis, sparteine, or strophanthus, hordenine has the advantage of being much less toxic. It has been found valuable in cases of typhoid, dysentery, enteritis, etc.—F. SODX.

Kola nut. L. Bernezau. Ber. deutsch. pharm. Ges., 1908, 18, 468—491.

THE first portion of this paper deals with the varieties of kola grown in different parts of Africa, and the means of transport to the markets. The kola fruit, after gathering, is stored in a sheltered place, when the outer shell splits open owing to fermentation, and the seeds can be removed. The seeds may be extracted with alcohol or sodium phosphate solution and the liquid or paste extract exported. The nuts, or rather seeds, can be preserved in hermetically sealed glass jars or tin boxes, which must be heated to 100° C. Peat dust makes a good packing for the seeds. The author claims priority for the method of sterilising the seeds described by A. Goris (this J., 1908, 996). "Kola red" was prepared from the seeds of *Cola acuminata* obtained from the Cameroons. The freshly-gathered fruit was allowed to stand for a few days and the seeds removed and crushed. They were mixed with sodium phosphate solution, allowed to stand overnight, and heated for 4 hours under pressure. The liquid extract was evaporated to a paste and extracted with dilute alcohol containing a little hydrochloric acid. The alcohol was distilled off, the residue taken up with water, and shaken with ether. The aqueous portion left a ruby-red substance on evaporation. This substance when heated with water loses its colour and forms phloroglucinol.—F. SODX.

Cyanogenetic glucosides [phaseolunatin]; Transformation of — during germination. L. Guignard. Compt. rend., 1908, 147, 1023—1028.

IN order to obtain evidence as to whether the cyanogenetic glucosides function as reserve material, the author has followed the transformation of phaseolunatin (linamarin) during germination of the beans of *Phaseolus lunatus*. When kept in the dark, these beans lose about one-fourth of their glucoside during the period of germination proper (a fortnight) and about one-third in a month, as measured by the amount of hydrocyanic acid obtainable; in the plants exposed to the light, this loss is more than counterbalanced, after the first ten days, by the synthesis of hydrocyanic acid effected in the leaves under the influence of chlorophyll. No evidence has been obtained that hydrocyanic acid is liberated during germination by the action of the enzyme present.—F. SODX.

Lavender oil; Adulteration of — with the esters of fatty acids of cocoanut oil. T. Delphin. Svensk. farm. Tidskrift, 1908, [22]; Pharm. Zeit., 1908, 53, 984.

THE presence of the esters of the fatty acids of cocoanut oil has been detected in a specimen of adulterated lavender oil. Owing to the high saponification value of these esters, the addition of a relatively small amount would materially increase the ester value of lavender oil of poor quality.—J. O. B.

Lemon oil. Schimmel's Rep. Noy. 1908, 60—65.

IT is pointed out that the solubility test of the Japanese Pharmacopœia (1 vol. of oil to form a clear solution with about 7 parts of 90—91.2 per cent. alcohol), whilst quite useless for detecting adulteration, would in many cases lead to the rejection of oils of the best quality.—A. S.

Lemon grass oil. Watt and Tempany. West. Ind. Bull., 9, 265; Pharm. J., 1908, Dec. 26, 840.

THIS oil, commonly known as oil of verbena, obtained from *Cynopogon citratus*, is known to vary in its solubility in

alcohol. It appears from the statements made by the authors that the West Indian oil is objected to on account of its imperfect solubility in alcohol. When first distilled, it is miscible with 95 per cent. alcohol up to one and a half times the volume of oil, but a further addition of oil causes turbidity. It has been found that, immediately upon distillation, West Indian lemon-grass oil is completely soluble in 95 per cent. alcohol without turbidity, but in a few days it loses this property, and will not give clear mixtures if the volume of alcohol be increased beyond about twice the volume of oil. This is now considered to be probably due to the polymerisation of some hydrocarbon, possibly myrcene. The Indian oil of the grass, *Cymbopogon flexuosus*, cultivated on the East Indian coast, near Cochin, does not possess this drawback, the oil being completely soluble in alcohol, and having a higher citral content than the West Indian oil. This grass is now under cultivation in the Leeward Islands at the botanic stations, so that in course of time a soluble oil may be produced in the West Indies, if the price obtainable, which is very low at present, offers encouragement for the cultivation of the grass.

Lemon-grass oil; [Determination of citral in —.] Schimmel's Rep., Nov., 1908, 80—84.

In the determination of citral in lemon-grass oil, where sodium bisulphite is used, this combines also with the

Oil of Thuja plicata (red cedar). I. W. Brandel and A. H. Dewey. Pharm. Review, 1908, 26, 248. Schimmel's Rep., Nov., 1908, 117—118.

In connection with the question of the utilisation of the waste products obtained in the clearing of large tracts of land in the north-west of the United States, the authors examined the oil from the red cedar. On distillation with steam, the leaves and twigs of the tree yielded 0.18—1.4 per cent. of a bright yellow oil having a slightly pungent, camphor-like odour, and possessing the following characters:—Sp. gr. at 25° C., 0.9305; $\alpha_D = -6.9$ at 25° C. in a 100 mm. tube; acid value, 0.518; saponification value, 5.7; ester value after acetylation, 6.2. The oil was miscible in all proportions with 70 per cent. alcohol. On distillation, more than 75 per cent. of the oil passed over between 190° and 203° C.; all the fractions were dextrorotatory. The oil contained about 3 per cent. of terpenes, among which pinene was identified, and also thujone, fenchone, and bornyl ester or esters. (See also Blasdale, this J., 1907, 635.)—A. S.

Savin oil; Detection of —. A. Beythien and P. Atenstädt. Z. Untersuch. Nahr. Genussm., 1908, 16, 677—679.

THE characters of savin, juniper wood, and juniper berry oils are given in the following table:—

Oil.	Sp. gr. at 15° C.	Specific rotation $[\alpha]_D$	Butyro-refractometer reading at 25° C.	Iodine value.	Saponification value.	Boiling point (not constant).
Savin	0.9137	+50	70.00	232.21	120.30	°C. above 165 (begins at 170)
Juniper wood	0.8727	+7.3	71.20	313.80	313.80	partially below 165 (begins at 155)
Juniper berry	0.8571	+5.95	64.00	329.44	329.44	below 165 (the largest portion between 155 and 165)

other aldehydes present in the oil and also with a part of the methylheptenone. Hence the bisulphite method gives results higher by from 2 to 5.5 per cent. than when normal sodium sulphite is used. Since lemon-grass oil is purchased on the basis of its citral-content, the method used to determine this should always be stated.—A. S.

Bergamot oil. Schimmel's Rep., Nov., 1908, 58—60

ACCORDING to the Japanese Pharmacopœia, 1 vol. of bergamot oil when mixed with 1.5—2 vols. of a mixture of 80 c.c. of alcohol and 10 c.c. of water at 20° C., should yield a clear solution, which may become turbid, but from which no oily drops should separate. It is pointed out that authentic oils of the best quality are frequently met with, which will fail to pass this test.—A. S.

Oil of dill herb. Schimmel's Rep., Nov., 1908, 19—50.

THE dextro-rotatory oil had a greenish-blue colour, and was soluble in 3.4 vols. of 90 per cent. (by vol.) alcohol. It had the sp. gr. 0.9062 at 15° C., and $n_D^{20} = 1.49185$. On distillation at 4 mm. pressure, 75 per cent. of the oil passed over between 45° and 60° C., and 20 per cent. between 130° and 132° C.; the lower-boiling fraction had the sp. gr. 0.8528 at 15° C., and optical rotation, $\alpha_D = +68.17^\circ$ in a 100 mm. tube. The oil contains *d*- α -phellandrene, terpinene, (and possibly also dipentene or limonene), earvone, and dill apiol, together with a blue substance identical with that which is the cause of the blue colour of some other essential oils such as camomile oil. When the oil is allowed to stand for a long time, clear long prisms, m. pt. 40°—44° C., separate from it; these are probably crystals of dill isapiol.—A. S.

The differences in the sp. gr. and on fractional distillation and the high saponification value and specific rotation are thus the best means for the detection of savin oil in the other oils. The specific rotation will also afford information in the case of conifer oil or turpentine oils being present, since with the exception of certain American turpentine oils, these are either optically inactive or levorotatory. The most reliable test of all, however, is the characteristic odour, and comparative tests have shown that it is possible in this way to detect as little as 0.1 per cent. of savin oil in mixtures of the two juniper oils. The odour is rendered most pronounced by diluting the oil with water and then heating it.—C. A. M.

Oil of maali resin. Schimmel's Rep., Nov., 1908, 137—139.

MAALI resin, a soft, elemi-like resin from Samoa, when distilled with steam, yielded 16.08 per cent. of a bright green semi-solid oil soluble in about 1 vol. of 90 per cent., or 3 vols. of 80 per cent. alcohol. The oil melted between 65° and 80° C. and had the optical rotation, $\alpha_D = +7.15^\circ$ in a 100 mm. tube; saponification value, 3.3; ester value after acetylation, 46.6. The solid portion of the oil yielded a new sesquiterpene alcohol, $C_{15}H_{26}O$, which when purified by crystallisation from 70 per cent. alcohol or petroleum ether, was obtained in silky needles, m. pt. 105° C., $[\alpha]_D = +18.33^\circ$; b. pt., about 260° C., ester value after acetylation, 16.0. When heated with dehydrating agents, this yielded the corresponding sesquiterpene, sp. gr. 0.9190 at 15° C., $[\alpha]_D = +131.99^\circ$, $n_D^{20} = 1.52252$, b. pt. 270.8—271° C. (754 mm.). The liquid portion of the oil apparently consisted of a solution of the solid sesquiterpene alcohol in a levorotatory sesquiterpene. The sesquiterpene alcohol yielded with chromic acid an addition compound, $(C_{15}H_{24}O)_2CrO_3$,

which melted at 111 C., was soluble in most organic solvents, and was immediately decomposed by water. Other sesquiterpene alcohols also formed addition compounds with chromic acid.—A. S.

Camphor substitutes: *Analysis of camphorated oil for* —, F. W. Richardson and W. Walton, *Analyst*, 1908, **33**, 463—466.

NATURAL camphor can be determined in camphorated oil by direct polarimetry (see Leonard and Smith, this J., 1900, 861). "The reading given in a 100-mm. tube in a Schmidt and Haensch instrument, multiplied by 0.69, gives the percentage of camphor in camphorated oil on the volume. This figure divided by 0.926—the sp. gr. of the oil at 15.5 C.—gives grms. of camphor in 100 grms. of the oil." Synthetic camphor was found to have a molecular weight of 150.6 (theory for camphor, 152.016), and to agree with ordinary camphor in all other respects, except that it is optically inactive. For the analysis of oils containing such substitutes, 10 grms. of the sample are heated in a 2-oz. retort in an oil-bath at 200 C., a current of carbon dioxide being meanwhile passed through the retort. The delivery tube of the retort is connected with a weighed 4 oz. Woulfe's bottle, which is placed in ice, and a small spiral glass condenser of known weight is fitted by means of a cork into the other opening of the bottle. The bulk of camphors present will condense in crystals in the delivery tube of the retort, and the portion of the tube may subsequently be cut off with a file and weighed. The sublimate is then dissolved off the glass by means of carbon tetrachloride, and its weight found by again weighing the dried portion of the retort. Any additional volatile products will be in the Woulfe's bottle and spiral condenser, and the increase in weight of these gives their quantity. These portions are also dissolved in carbon tetrachloride and added to the original solution. The whole solution is then weighed, and aliquot portions taken for the determination of the sp. gr. and iodine value, and for polymerisation with sulphuric acid. For the last-named test about half the solution is treated little by little with a third of its volume of sulphuric acid (sp. gr. 1.81), and the whole then thoroughly mixed, cooled if necessary, and allowed to stand for 5 minutes. The side tube of the flask containing the solution is then connected with a Liebig's condenser, the outlet of which is connected with an 8 oz. separator, and a current of steam is passed through the apparatus until the separator is nearly full. The condenser tube is rinsed out with some of the carbon tetrachloride drawn from the lower layer in the separator, and subsequently with fresh solvent, and the united carbon tetrachloride solutions are transferred to a flask and weighed. About 35 per cent. of the camphors are unaltered by the treatment with sulphuric acid and distil, whilst turpentine and essential oil of camphor are polymerised to such an extent that no optically active substance subsequently passes over. The amount of total camphors may be calculated from the change in the specific gravity and refractive index of the carbon tetrachloride solution, whilst the natural camphor is found by multiplying the polarimetric reading in a 200 mm. tube by 0.22385 and dividing the product by 0.95. If the solution is optically inactive, natural camphor is absent. In calculating results from the iodine value it is assumed that the normal value of natural camphor is 5, that of artificial camphor 7, that of essential oil of camphor 180, and that of oil of turpentine 370. Essential oil of camphor, when present to any notable extent, may be detected by the odour emitted on heating the solution. The olive oil freed from the volatile constituents by being heated at 200 C. in a current of carbon dioxide is not changed as regards its physical characteristics and iodine value, and the constants due to the oil itself may thus be eliminated from the values obtained with the original camphorated oil. The proportion of turpentine or oil of camphor may be calculated from the iodine value, when the amounts of natural and synthetic camphor are known. The accuracy of this method is shown by test analyses of mixtures of olive oil with various proportions of the four other substances.—C. A. M.

l-Pinene: *Action of piperidine on the nitrosochloride of* —, P. Golubew, J. Russ. Phys.-Chem. Ges., 1908, **40**, 1015—1018. *Chem. Zentr.*, 1908, **2**, 1865—1866.

A CUSTOMARY method for the identification of pinene consists in the preparation of its nitrosochloride and the compound of the latter with piperidine. Wallach has previously shown (*Annalen*, **245**, 251) that the reaction between *d*-pinene-nitrosochloride and piperidine proceeds in two directions, and the author finds that this is also the case with the nitrosochloride of *l*-pinene (obtained from the oil of the Siberian fir). Ten grms. of *l*-pinene-nitrosochloride (m. pt. 103—104 C.) were mixed with an equal weight of piperidine and 30 c.c. of alcohol, and the mixture boiled and then treated with water. The precipitate was dissolved in glacial acetic acid, and water added until a crystalline precipitate separated; this consisted of nitrosopinene (m. pt. 134—135 C.). From the filtrate *l*-pinenitropiperidide, $C_{10}H_{16}NO.NC_5H_{10}$, was precipitated by ammonia and purified by crystallising from ether; it melted at 118—119 C. The relative yields of *l*-nitrosopinene and *l*-pinenitropiperidide were 35.5 and 54.9 per cent. respectively. From French oil of turpentine a yield of 39.8 per cent. of *l*-nitrosopinene was obtained.—A. S.

Iodine derivative [iodopeptide]: *New* —, A. Cecchini, *Giorn. Farm. Chim.*, 1908, **57**, 441—444. *Chem. Zentr.*, 1908, **2**, 1891.

BY the action of iodine (in the nascent condition) on a peptonised albumin solution (10:100), the author obtained a new iodine preparation, *iodopeptide*, containing from 1.75 to 3.48 per cent. of iodine. The new product is a pale yellow liquid, apparently a colloidal solution. It is stated to be useful in tuberculous diseases.—A. S.

Methyl alcohol: *Dehydration of commercial* —, J. Cyr, *Ber.*, 1908, **41**, 4322—4327.

STARTING from a commercially pure methyl alcohol, free from acetone, the anhydrous alcohol may be prepared by first boiling for a long time with quicklime, then allowing the liquid to stand for some weeks over ignited potassium carbonate, and finally distilling several times in presence of metallic calcium. During these manipulations the alcohol must be protected from moist air by a tube filled with calcium chloride or phosphorus pentoxide. In the first distillation, 10 grms. of metallic calcium turnings are used for 1 litre of alcohol; the liquid is digested near the boiling point for some time before distillation takes place. In the subsequent distillations smaller quantities of calcium are taken, since, as the alcohol becomes nearly anhydrous, it tends to react very vigorously with the calcium, with considerable evolution of heat. Three or four distillations from calcium are sufficient to give anhydrous alcohol. The condition of the alcohol may be ascertained by determining its esterification velocity with phenyl-acetic acid in presence of hydrogen chloride. The elimination of the moisture is accompanied by a rise in the esterification constant until the alcohol is anhydrous. The presence of 0.125 per cent. of moisture was found to lower the esterification constant by 13 per cent., whereas its influence on the sp. gr. was only 0.055 per cent. The sp. gr. at 15°/15° C. of anhydrous methyl alcohol is 0.79647; its boiling point is 64.56° C.—J. F. B.

Urano-uranic oxide, and a standard of radio-activity. H. N. McCoy and G. C. Ashman. *Amer. J. Sci.*, 1908, **26**, 521—530.

URANO-URANIC oxide, U_2O_5 , may be obtained in a pure condition by heating any higher or lower oxide to constant weight at about 700° C. Uniform films of this oxide, 7 cm. in diameter and weighing 0.6—0.8 gm., have been found to exhibit very definite and constant α -ray activity. These films are easily reproduced and are sufficiently thick to have the maximum α -ray activity; they are, therefore, recommended as standards. From the results

of measuring, in absolute units, the α -ray saturation current for such a standard film, the total ionisation current for 1 grm. of uranium, in an infinitely thin film, has been calculated to be 4.61×10^{-10} amp. The α -ray activity of radium (free from its products) is 1.29×10^6 times that of an equal weight of uranium.—F. SODN.

Thorium; Chlorides and oxychlorides of —. E. Chauvenet. *Compt. rend.*, 1908, **147**, 1046—1048.

ANHYDROUS thorium tetrachloride is best prepared from thoria by heating in a very slow stream of phosgene. The chloride sublimes as prismatic needles which absorb water readily from the air, without changing in appearance. The crystals, when heated in a stream of phosgene, sublime as a very hygroscopic white powder of the same composition. An aqueous solution of the chloride, on evaporation, gives the hydrate, $\text{ThCl}_4 \cdot 7\text{H}_2\text{O}$. Thorium chloride is readily oxidised, for on heating the above hydrate in a stream of dry hydrogen chloride at 120° — 160° C. till of constant weight, the compound, $\text{ThO}(\text{HCl})_2 \cdot \text{H}_2\text{O}$, is obtained, and at 250° C. the compound, ThOCl_2 .—F. SODN.

Thorium chloride; Preparation of —. C. Matignon. *Compt. rend.*, 1908, **147**, 1292—1293.

DELÉPINE and the author proposed to prepare thorium chloride by the action on thoria at a high temperature of a mixture of carbon monoxide and chlorine; Chauvenet proposed to substitute carbonyl chloride for this mixture, and Delépine and the author suggested, later, a mixture of chlorine and carbon tetrachloride. The action of chlorine and sulphur dichloride, however, is preferable to any of these processes, as it occurs at a lower temperature, so that glass tubes can be used, and oxychloride is not formed to the same extent. Quite recently, the author has tried the chlorides of phosphorus, but the results are not so good as with sulphur chloride. The extraordinary hygroscopicity of thorium chloride is due to impurities; the pure chloride, though it is hygroscopic, can nevertheless be manipulated in the air quite safely. Its heat of solution (1 molecule in 2700 of water) was found to be 53.8 calories.—J. T. D.

Tannic and gallic acids; Action of reducing agents on —.

Phenols; Action of iodine on — and a modified process for the determination of tannic acid. W. M. Gardner and H. H. Hodgson. See XIV.

PATENTS.

Secretions from organic tissues; Process for obtaining —. E. Hoenicke, Dresden, Germany. Eng. Pat. 26,918, Nov. 23, 1907. Under Int. Conv., Nov. 30, 1906.

THE sodium chloride solution containing the secretion (see Eng. Pat. 27,023 of 1907; this J., 1908, 1084) is either filtered through a Berkefeld or other fine-grained filter, which allows the contents of the vesicle to pass through but retains the cellular albumin, or is dialysed through a suitable membrane such as parchment paper. Or the tissue to be treated may be introduced into a finely porous filter or enclosed in a casing of a suitable membrane placed in a solution of common salt, in order to carry out the filtration or dialysis simultaneously with the maceration.—T. H. P.

Secretions from organic tissues; Process for obtaining —. E. Hoenicke, Dresden, Germany. Eng. Pat. 24,750 of 1908; date of application, Nov. 23, 1907.

THE liquid containing the secretion (see Eng. Pat. 27,023 of 1907; this J., 1908, 1084) is submitted to dialysis through a suitable animal membrane, such as thin intestine, by which the colloidal cellular albumin is retained and so separated from the diffusible secretions.—T. H. P.

Cyclic carbonates of halogen derivatives of ethyl- and propyl-3,4-dihydroxybenzene. H. S. Wellcome, London, and G. Barger, Herne Hill. Eng. Pat., 2023, Jan. 29, 1908.

WHEN 3,4-methylenedioxy styrene is treated with chlorine at 0° C., a dichloride is formed, which boils at 153° — 160° C. at 12 mm. This is changed by aqueous acetone into

the corresponding chlorhydrin, which melts at 95° C. When either of these substances is treated with phosphorus pentachloride, distilled, and the product mixed with anhydrous formic acid, the cyclic carbonate of α -3,4-dihydroxyphenyl- α -3-dichloroethane, $\text{O} : \text{C} : \text{O}_2 : \text{C}_6\text{H}_3 \cdot \text{CHCl} \cdot \text{CH}_2\text{Cl}$, is obtained. This carbonate forms a thick oil boiling at 182° C. at 8 mm. Starting from isosafrolchloride and using an analogous process, the cyclic carbonate of α -3,4-dihydroxyphenyl- α -3-dichloropropane, $\text{O} : \text{C} : \text{O}_2 : \text{C}_6\text{H}_3 \cdot \text{CHCl} \cdot \text{CHCl} \cdot \text{CH}_3$, is produced. This substance boils at 192° C. at 9 mm.—F. SODN.

Therapeutic compound [Hydroxyquinoline salicylate]; New —. H. S. Wellcome and A. G. Bates, London, and F. G. P. Reinfry, Dartford. Eng. Pat. 8068, April 11, 1908.

ONE molecular proportion of salicylic acid in alcohol is added to one molecular proportion of 8-hydroxyquinoline also dissolved in alcohol. On evaporation, crystals of 8-hydroxyquinoline salicylate, $\text{C}_{16}\text{H}_{13}\text{O}_4\text{N}$, separate, which melt at 114° — 115° C. after crystallising from acetone.—F. SODN.

Radio-active mass. S. Loewenthal, Braunschweig, and K. Lüer, Charlottenburg, Assignors to Radiogen Ges.m.b.H., Charlottenburg, Germany. U.S. Pat. 907,066, Dec. 15, 1908.

A BLOCK of kieselguhr containing incorporated radio-active substances is enclosed in a cover of kieselguhr, and the whole is arranged in a reservoir so as to close the outlet opening of the latter. Any fluid drawn off from the reservoir has therefore to pass through the radio-active block.—A. S.

Borneols and isoborneols or their esters from pinene; Process for preparing —. G. Austerweil. Fr. Pat. 392,159, June 15, 1908. Under Int. Conv., May 13, 1908.

PINENE is heated under pressure in an autoclave with an aromatic polysubstituted acid, which is insoluble or slightly soluble in water, to a temperature 10° or 20° above the boiling point of the mixture: the air in the autoclave is replaced by carbon dioxide or other inert gas, which is forced in until a suitable pressure is attained. Addition of a small quantity of the anhydride or chloride of the acid accelerates the reaction. The excess of acid is removed from the resulting product by filtration, and the limonene separated from the oily portion by steam distillation: the residue, which consists of esters of borneol and isoborneol, may then be saponified.—T. F. B.

Camphor; Manufacture of artificial —. G. A. Le Roy. Fr. Pat. 392,182, Sept. 17, 1907.

TURPENTINE oil is treated with a halogen at a low temperature (e.g., -25° C.), until an increase of 25 to 50 per cent. of its weight is obtained. The product is mixed with one-eighth to one-fifth of its weight of sodium hydroxide, the temperature meanwhile being kept low, when it is said to be converted into camphor.—T. F. B.

Isobornyl esters from pinene hydrohalides; Process for preparing —. L. Weitz. Fr. Pat. 392,247, July 11, 1908. Under Int. Conv., July 12, 1907.

PINENE hydrohalides are converted into isobornyl esters by heating with organic acids in presence of metallic zinc: camphene is formed during the process, and combines with the acid, forming an isobornyl ester. It is stated that the yields are 20 to 30 per cent. higher than when organic zinc salts are used for the purpose. The following is an example of the process:—172 kilos. of pinene hydrochloride and 350 kilos. of glacial acetic acid are heated to 90° — 95° C., and 40 to 45 kilos. of zinc foil are added: evolution of hydrogen continues quietly for about 20 hours, after which the excess of acetic acid is removed by distillation under reduced pressure, and the isobornylacetate is washed.—T. F. B.

Powders, tablets, etc., completely soluble in water; Preparation of — containing substances originally insoluble. L. J. Barillet. Fr. Pat. 392,478, July 20, 1908.

ESSENTIAL oils, tar oils, etc., are mixed with a sulpho-ricinoleate and about 20 times their weight of lactose; the resulting products are said to be soluble in water.

T. F. B.

Bromisovaleric acid ester of isobornol; Manufacture of the —. A. Zimmermann, London. From Chem. Fabr. auf Actien, vorm. E. Schering. Eng. Pat. 1682, Jan. 24, 1908.

XXII.—EXPLOSIVES, MATCHES, &c.

Compressed powder, nitroglycerin and ammonium nitrate explosives; Experiments with — in the Royal Coal-mines, Schwalbach (Saar). Glückauf, 1908, 44, 1566—1571.

EXPERIMENTS were made as to the relative cost and coal-getting power of compressed powder compared with the following explosives: *Roburite* No. 3; ammonium nitrate (55), trinitrotoluene (12), flour (6), magnesium carbonate (5), sodium chloride (7), ammonium chloride (5), potassium nitrate (9.5), and potassium permanganate (0.5 parts). *Wittenberger Wetterdynamite*: nitroglycerin (25), potassium nitrate (34), rye meal (38.5), wood meal (1), barium nitrate (1), and sodium carbonate (0.5 parts), *Carbonite* No. 1: nitroglycerin (25), sodium nitrate (30.5), wheat flour (39.5), and potassium bichromate (5.0 parts).

The following table gives the comparative results.

Conditions of mining.	Consumption of explosives in grams per ton of coal produced.			Taking compressed powder as unity.	
	Compressed powder, grams.	Other explosives.	grams.	Consumption.	Cost.
With undercut	149	Carbonite	36	0.64	0.87
	117	Wetterdynamite	98	0.83	1.14
	180.5	Roburite	128.8	0.69	1.24
With breaking-in shots	190	Wetterdynamite	51	0.27	0.37
Without undercut or breaking-in shots	149	Carbonite	137	0.42	1.25
	86.5	Wetterdynamite	79.0	0.46	1.31
	84	Roburite	87	1.03	1.85

Safety explosives; Tests with —. Beyling. Glückauf, 1908, 44, 1717—1721.

THESE tests were carried out in the testing station at Gelsenkirchen, where the principle has always prevailed that explosives should be subjected to as rigorous tests as possible. Hitherto air containing 8 to 9 per cent. of fire-damp was used, and 2 litres of fine coal dust were added just before firing. Under these conditions coal dust appeared to exert no special influence on the result of the tests. In 1907 it was found however that coal dust is more readily ignited by quite a number of explosives than the most sensitive fire-damp mixture (see Beyling, Glückauf, 1907, Nos. 36 and 37), and further, that certain other explosives ignite a fire-damp mixture more readily than a fire-damp mixture containing coal dust. Tests have been carried on since, and it was found that all explosives ignite either coal dust or a gas mixture more readily than a combination of the two. This is explained by the fact that any addition of coal dust to the most sensitive mixture of air and fire-damp immediately reduces the amount of oxygen available for the combustion of the fire-damp, and so renders the whole less sensitive. It was therefore decided to make fresh tests for the whole range of safety explosives on this principle. The work is not yet complete, but the results of the tests on some explosives belonging to the gelatin-dynamite and ammonium nitrate groups (largely used in mines on account of their efficiency) are published in tabular form. The shots were fired from a mortar of 55 mm. diameter into air containing 8 to 9 per cent. of fire-damp. The cartridges were of 35 mm. diameter and no stemming was used. Not more than 150 grms. of any of the explosives tested could be fired without causing ignition, while in most cases 50 grms. sufficed. On the other hand, the maximum capacity of the mortar (600—800 grms. according to the density of the explosive) fired into coal dust did not cause ignition. Recently, "Kohlencarbonit," "Wittenberger Wetterdynamit," and "Ammoncarbonit" were tested. The two former are said to be almost identical in composition, and quantities of 650 grms. (the maximum capacity of the mortar) were found to be safe both in fire-damp, and in coal dust. "Ammoncarbonit" ignited, it is stated, in fire-damp when

500 grms. were used, but was safe with 450 grms., whilst in coal dust the values were given as 300 grms. and 250 grms. respectively.—C. J. G.

White Phosphorus Matches Prohibition Act, 1908. [8 Edw. 7. Ch. 42.]

THE following is the text of the above Act to prohibit the manufacture, sale, and importation of matches made with white phosphorus, and for other purposes in connection therewith, dated Dec. 21, 1908:—

1.—(1) It shall not be lawful for any person to use white phosphorus in the manufacture of matches, and any factory in which white phosphorus is so used shall be deemed to be a factory not kept in conformity with the Factory and Workshop Act, 1901, and that Act shall apply accordingly.

(2) The occupier of any factory in which the manufacture of matches is carried on shall allow an inspector under the Factory and Workshop Act, 1901, at any time to take for analysis sufficient samples of any material in use or mixed for use, and, if he refuses to do so, shall be guilty of obstructing the inspector in the execution of his duties under that Act:

Provided that the occupier may, at the time when the sample is taken, and on providing the necessary appliances, require the inspector to divide the sample so taken into two parts and to mark, seal, and deliver to him one part.

2. It shall not be lawful for any person to sell or to offer or expose for sale or to have in his possession for the purposes of sale any matches made with white phosphorus, and, if any person contravenes the provisions of this section, he may on complaint to a court of summary jurisdiction be ordered to forfeit any such matches in his possession, and any matches so forfeited shall be destroyed or otherwise dealt with as the court may think fit, but this provision shall not come into operation as respects any retail dealer until the first day of January, nineteen hundred and eleven.

3. It shall not be lawful to import into the United Kingdom matches made with white phosphorus, and matches so made shall be included amongst the goods enumerated and described in the table of prohibitions and restrictions contained in section forty-two of the Customs Consolidation Act, 1876.

4.—(1) Any person who is manufacturing or proposing to manufacture matches by way of trade may present a petition to the Board of Trade, praying for the grant of a compulsory licence to use any process patented at the passing of this Act for the manufacture of matches without white phosphorus, other than matches intended to strike only on a surface specially prepared for the purpose.

(2) The Board of Trade, after considering any representations that may be made by the patentee as defined by the Patents and Designs Act, 1907, and any person claiming an interest in the patent as exclusive licensee or otherwise, and, after consultation with the Secretary of State, may order the patentee to grant a licence to the petitioner on such terms as the Board may think just. The provisions of the Board of Trade Arbitrations, &c., Act, 1874, shall apply to proceedings under this section as if this Act were a special Act within the meaning of that Act.

(3) An order of the Board directing the grant of a licence under this section shall, without prejudice to any other method of enforcement, operate as if it were embodied in a deed granting a licence and made between the petitioner and the patentee and such other persons claiming an interest in the patent as aforesaid.

5.—(1) This Act may be cited as the White Phosphorus Matches Prohibition Act, 1908, and shall, except as otherwise expressly provided, come into operation on the first day of January nineteen hundred and ten.

(2) For the purposes of this Act the expression "white phosphorus" means the substance usually known as white or yellow phosphorus.

Chlorazide, N₂Cl. F. Raschig. See VII.

PATENTS.

Explosives; Manufacture of —. South African Maganite Explosives Synd. Ltd., and H. C. L. Bloxam, Cape Town. Eng. Pat. 26,823, Dec. 4, 1907.

The process claimed is an improvement on that described in Eng. Pat. 3005 of 1906 (this J., 1906, 868), and consists in fusing ammonium nitrate, allowing it to solidify, grinding it and mixing it with dinitrobenzene, the mixture being heated to a temperature a little above the melting point of dinitrobenzene.—A. S.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUANTITATIVE.

Nickel; Electrolytic determination of —. A. Schumann. Z. angew. Chem., 1908, 21, 2579—2583.

PARALLEL experiments showed that a gauze cathode is preferable to a dish or cone cathode in the electrolytic determination of nickel. Good results were obtained by electrolysing solutions of nickel-ammonium sulphate in presence of ammonia, ammonium carbonate, or sodium pyrophosphate and ammonium carbonate, with all three cathodes; with solutions of nickel-ammonium sulphate containing boric acid, good results were obtained with a dish or gauze cathode, but not with a cone cathode; solutions of the same salt to which oxalic acid was added gave very high values, due to the deposition of carbon, both at the ordinary temperature and at 60–70° C.; in presence of citric acid, solutions of nickel-ammonium sulphate, electrolysed at 60–70° C., gave low results, although carbon was deposited; from solutions of the same salt containing free sulphuric acid or hydrochloric acid, firmly adherent deposits were obtained, the results, however, being useless for quantitative work. Solutions of nickel chloride to which ammonia was added gave good results with the dish and gauze cathodes, but not with the cone cathode, unless ammonium sulphate was added as well. Solutions of nickel nitrate also gave good results if a large excess of ammonia and a considerable quantity of ammonium sulphate, or ammonium sulphate and ammonium nitrate, were added, and the electrodes were kept sufficiently far apart.—A. G. L.

Rotating anode; Use of the — in electrolytic separations. [Determination of cadmium.] M. E. Holmes. J. Amer. Chem. Soc., 1908, 30, 1865—1874.

SATISFACTORY separations can be made with the rotating anode, using low currents (0.3–1 amp.), and in much less time than is required with stationary electrodes. Cadmium has been separated from aluminium, chromium, cobalt, nickel, zinc, and magnesium in the presence of sulphuric acid, from manganese in the presence of formic acid, and from aluminium and magnesium in the presence of ammonium acetate and acetic acid, precipitation being complete in about 45 minutes. Attempts to separate cadmium from iron proved unsuccessful (compare this J., 1904, 1115).—F. SOHN.

ORGANIC—QUALITATIVE.

Guaiacum reaction; *Contribution to the knowledge of the* ——. C. L. Alsberg. *Arch. exp. Pathol. u. Pharmak.*, 1908, Supplementband. Schmiedeberg-Festschrift, 39—53. *Chem. Zentr.*, 1908, 2, 1955.

THE author has found that the blue coloration of guaiacum tincture in presence of hydrogen peroxide is produced by many chlorides, including alkali chlorides, but not by sulphates or nitrates. In certain cases metal ions (iron, copper, etc.) act catalytically in producing the coloration. The guaiacum-hydrogen peroxide reaction is thus not a trustworthy means for the detection of oxydases or peroxydases.—A. S.

Savin oil; *Detection of* ——. A. Beythien and P. Atenstädt. *See XX.*

ORGANIC—QUANTITATIVE.

Sodium peroxide; *Use of* — in organic analysis. H. Pringsheim. *Ber.*, 1908, 41, 1267—1271. (Compare this J., 1905, 943.)

THE author cites a number of well-agreeing analyses in support of his contention that Virgin's recent statement (*Arkiv. kemi. Geol.*, 1908, 3, 112) that oxidation with sodium peroxide is not suitable for the estimation of halogens in organic compounds cannot be upheld. The following is an improved method of carrying out the analysis: The substance is mixed in an iron crucible with the requisite amount of sodium peroxide, fused, and mixed with an iron nail inserted through a hole in the crucible lid by means of crucible tongs. Substances containing 75 per cent. and more of carbon, hydrogen, and sulphur require 18 times, and those with 50—75 per cent. of these elements 16 times their weight of sodium peroxide. Those containing 25—50 per cent. of these elements are mixed with half, and those with less are mixed with an equal weight of a substance containing much carbon and hydrogen, for example, sugar, and then with 16 times in the former case and 18 times in the latter, their weight of sodium peroxide. After cooling, the crucible is transferred to a dish containing water reaching to about three-quarters of the height of the crucible and covered with a watch-glass; the mass dissolves gradually. (a) Sulphur is estimated by acidifying with hydrochloric acid, filtering, and adding barium chloride. (b) Halogens are determined by adding 3 c.c. of a saturated solution of sodium sulphite or bisulphite (to reduce any halogen oxy-acids formed), then dilute sulphuric acid until any iron precipitate is dissolved, heating to expel sulphur dioxide, and adding first 3 c.c. of concentrated nitric acid, and then silver nitrate. The silver halide is weighed in a Gooch crucible. (c) Arsenic and phosphorus are best estimated by using a silver crucible; the solution is acidified with hydrochloric acid, filtered, ammonia added, and precipitation effected with magnesia mixture.—J. C. C.

Tannic and gallic acids; *Action of reducing agents on* ——. *Phenols*; *Action of iodine on* —— and a modified process for the determination of tannic acid. W. M. Gardner and H. H. Hodgson. *See XIV.*

New Books.

SOME ELECTRO-CHEMICAL CENTRES. A Report to the Electors of the Gartside Scholarships. By J. N. PRING, M.Sc. Sherratt and Hughes, the University Press, Manchester. 1908. Price 1s. 6d.

THE report is based chiefly on information acquired during visits to several European countries, to the United States, and Canada, including British Columbia, during the years 1907 and 1908.

Six volume, containing 136 pages of subject-matter, and an alphabetical index. The subject-matter is classified as follows:—I. Cost of power production. II. Niagara Falls. III. The copper refineries of New Jersey. IV. Canadian water powers and electro-chemical centres. V. Electric smelting of iron ores, and steel production. VI. Ozone and water purification. VII. Gold and silver refining. VIII. Electrical manufacture of carbon bisulphide. IX. Electro-chemical industries in the Alps, France, and Belgium. X. The electrical fixation of atmospheric nitrogen. XI. Power centres and electro-chemical works in Great Britain.

SPRECHSAAL-KALENDER, FÜR DIE KERAMISCHEN, GLAS- UND VERWANDTEN INDUSTRIEN. 1909. I. Jahrgang. Herausgegeben von Dr. J. KOERNER, Müller und Schmidt, Verlag des Sprechsaal, Coburg. 1908. Price M.250.

THE first appearance of this Kalender. It is of pocket-book size, bound in waterproof cloth, and contains a calendar, blank pages headed for the months of the year, and each day of the month, besides 38 blank pages for miscellaneous entries. The technological portion which follows, fills 116 pages, devoted to all subjects likely to be of service to the ceramic, glass, and allied industries, to students of the subject, or to the practical chemist.

STATISTICAL ABSTRACT FOR FOREIGN COUNTRIES IN EACH YEAR FROM 1896 TO 1905 6, WITH SOME PROVINCIAL FIGURES FOR 1907. Thirty-fourth Number. [Cd. 4265.] Wyman and Sons, Fetter Lane, London, E.C. Price 1s. 7d.

THIS abstract gives particulars regarding trade, navigation, agriculture, railways, telegraph and telephone systems, finance, mineral production, &c., of the principal foreign countries for a series of years. This number of the abstract deals mainly with the years 1896 to 1906, but in the case of Germany, France, and the United States, it has been possible to include some particulars of the foreign trade of these countries for the year 1907. Four new tables summarising the trade of the principal commercial countries with the United Kingdom have also been included.

STATISTICAL ABSTRACT FOR THE SEVERAL BRITISH COLONIES, POSSESSIONS AND PROTECTORATES IN EACH YEAR FROM 1893 TO 1907. Forty-fifth Number. [Cd. 4115.] Wyman and Sons, Fetter Lane, London, E.C. Price 2s.

THIS publication contains the principal official data regarding the trade, shipping, agriculture, production, revenue, expenditure, &c., &c., of the various British Colonies, Possessions, and Protectorates, as well as an abstract of the rates of import duty levied in the various Colonies on the principal articles of trade.

COLONIAL IMPORT DUTIES, 1908. RETURN RELATING TO THE RATES OF IMPORT DUTIES LEVIED UPON THE PRINCIPAL AND OTHER ARTICLES IMPORTED INTO THE BRITISH COLONIES, POSSESSIONS, AND PROTECTORATES. [Cd. 4383.] Wyman and Sons, Fetter Lane, London, E.C. Price 3s.

THIS RETURN shows the duties in force, so far as notified to the Board of Trade, at the date of preparation of the Return, viz., November, 1908.

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 27,061. Perks. Moving valuable vapours or gases from machinery. Dec. 14.
 27,089. Donlton and Morson. Hand pump pressure filter.* Dec. 14.
 27,245. Norma Compagnie, and Kirner. Pyrometers.* Dec. 15.
 27,466. Hallett. Separating air or other gases from liquids.* Dec. 17.
 27,473. Panling. Simultaneously distilling and concentrating liquid mixtures.* Dec. 17.
 27,551. Snowden. Kilns.* Dec. 18.
 27,675. Schmatolla. Furnaces, kilns, etc. [Addition to No. 1168 of 1908.]* Dec. 19.
 27,767. Arbuckle and Osborne. *See under X.*
 27,939. Jones. Centrifugal machines for separating liquids from solid substances. Dec. 23.
 28,201. Dempster and Sons, Ltd., and Toogood. Vertical retorts. Dec. 28.
 28,295. Webb. Apparatus for filtering liquid. Dec. 28.
 28,549. Schmatolla. Kilns for burning limestone, dolomite, &c. Dec. 31.

COMPLETE SPECIFICATIONS ACCEPTED.

- 27,947 (1907). Black, Lennox, and Lennox. Apparatus for cleaning or washing smoke and for inducing draught. Dec. 23.
 28,079 (1907). Oxley and Crossley. Recovery and subsequent utilisation of the waste heat of kilns, ovens, etc. Dec. 31.
 28,356 (1907). Williamson. Centrifugal drying machines. Dec. 23.
 4540 (1908). Hawes. Obtaining dry products from liquids and semi-liquids. Dec. 23.
 7920 (1908). Peat. *See under X.*
 20,400 (1908). Arbuckle and Osborne. Rotary filtering apparatus. Dec. 31.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 27,144. Kroll and Saklatwalla. Production of pure and thin filaments for illuminating purposes. [Ger. Appl., Dec. 13, 1907.]* Dec. 14.
 27,755. Zdanowich. Incandescent mantles. Dec. 21.
 27,763. Kokotek, Knaster, and Offord. Bodies for incandescent lighting. Dec. 21.

- 27,841. Chandler. Apparatus for gas purification. Dec. 22.
 27,896. Paterson. Hydrocarbon gas production. Dec. 22.
 27,899. Lewis. Arc lamp electrodes. Dec. 22.
 27,920. Nehmer. Incandescent gas mantles. Dec. 23.
 28,032. Schmatolla. Gas producer. Dec. 24.
 28,053. Mason's Gas Power Co., Ltd., and others. Production of gas from bituminous fuel in gas producers. Dec. 24.
 28,054. Mason's Gas Power Co., Ltd., and others. Production of recoverable ammonia in the manufacture of producer gas. Dec. 24.
 28,179. Marshall. Manufacture of artificial fuel. Dec. 24.
 28,201. Dempster and Sons, Ltd., and Toogood. *See under I.*
 28,349. Rindom. Gas retorts. [App. in Denmark, July 16, 1908.]* Dec. 29.
 28,435. Laigle. Incandescent gas and electric filaments. [Swiss Appl., Jan. 10, 1908.]* Dec. 30.
 28,462. Neilson. *See under III.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 28,049 (1907). Fieschi. Coke furnaces. Dec. 31.
 28,290 (1907). Von Bauer. Coke ovens for the recovery of by-products. Dec. 23.
 28,602 (1907). White. Distillation of coal for producing smokeless fuel. Dec. 23.
 4956 (1908). Planchon. Manufacture of incandescent bodies for electric lamps. Dec. 23.
 7105 (1908). Junquera. Gas generators. Dec. 23.
 12,955 (1908). Hammond and Cash. Manufacture of gas. Dec. 23.
 15,042 (1908). Lake (Trump). Gas producers. Dec. 23.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATION.

- 28,462. Neilson. Purification of and recovery of tar and other substances from blast furnace, producer, and like gases.* Dec. 31.

COMPLETE SPECIFICATION ACCEPTED.

- 7920 (1908). Peat. *See under X.*

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

- 27,095. Knoll and Co. Phenolphthalein compounds. [Ger. Appl., Dec. 21, 1907.]* Dec. 14.
 27,098. Newton (Bayer and Co.). Manufacture of anthracene derivatives and their employment in dyeing and printing. Dec. 14.
 27,747. Imray. (Soc. Chem. Ind. in Basle). Manufacture of brominated indigos.* Dec. 21.
 28,272. Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matter.* Dec. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

- 5485 (1908). Newton (Bayer and Co.). Manufacture of sulphur dyestuffs. Dec. 23.
 7552 (1908). Holliday and Sons, and others. *See under V.*
 9107 (1908). Imray (Meister, Lucius, und Brüning). Separation of *o*- and *p*-chlorobenzaldehyde. Dec. 23.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

- 27,098. Newton (Bayer und Co.). *See under IV.*
 27,225. Levene and Harris. Rendering fabrics and other articles non-inflammable. Dec. 15.
 27,676. Pfel. Process for obtaining textile fibres.* Dec. 19.
 27,742. Newton (Bayer und Co.) Printing with brominated indigo. Dec. 21.
 27,928. Calico Printers' Assoc., and Hewit. Calico printing. Dec. 23.
 28,042. Hardman and Edmondson. Bleaching cotton or other vegetable fibres in the raw state or in yarns or fabrics. Dec. 24.
 28,056. Ryhance. Reducing the inflammability of textile fabrics. Dec. 24.
 28,149. Lecoœur. Manufacture of threads and filaments of cellulose. Dec. 24.
 28,163. Malcolmson (De Lamarre). Treatment of megass and other vegetable fibre. Dec. 24.

COMPLETE SPECIFICATIONS ACCEPTED.

- 3751 (1908). Johnson (Badische Anilin und Soda Fabrik). Production of reserve effects on fabrics in dyeing with sulphur colouring matters. Dec. 31.
 4295 (1908). Shaw, and Whitfield Velvet and Cord Dyeing Co. Dye jiggers or dyeing apparatus. Dec. 23.
 7552 (1908). Holliday and Sons, Turner, and Dean. Direct cotton dyestuff preparation for dyeing. Dec. 23.
 13,897 (1908). Drews. Extraction of fibre from leaves and other vegetable matter. Dec. 23.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

- 27,252. Rigby. Production of granulated or coarse-grained salt. Dec. 15.
 27,302. Carulla. Manufacture of ammonia salts from ferrous liquors. Dec. 16.
 27,587. Rollin, and Hedworth Barium Co. Manufacture of barium compounds. Dec. 18.
 27,592. Flamand. Dividing air into its elements by fractional distillation. [Fr. Appl., Sept. 18, 1908. Addition to No. 26,720 of 1908.]* Dec. 18.
 27,597. Morrison. Treatment and preservation of calcium carbide. Dec. 18.
 27,774. Rüber. Production of phosphate precipitates. [Appl. in Norway, Nov. 6, 1908.]* Dec. 21.
 27,878. Erlenbach. Manufacture of ammonium sulphate. [Ger. Appl., Jan. 10, 1908.]* Dec. 22.
 27,905. Woltereck, and The Sulphate of Ammonia Co., Ltd. Production of ammonia from peat. Dec. 22.
 28,054. Mason's Gas Power Co., Ltd., and others. *See under II.*
 28,074. Dewrance and Williams. Manufacture of alkaline cyanides. Dec. 24.
 28,112. Behrens. Separating carbonic acid from carbonic acid containing gas mixtures.* Dec. 24.
 28,549. Schmatolla. *See under I.*
 28,565. Jensen (Spitz). Production of pure oxide of tin. Dec. 31.

COMPLETE SPECIFICATIONS ACCEPTED.

- 14,285 (1907). Cowper-Coles. *See under XI.*
 27,463 (1907). Alexander, McClelland, and Lange. Unstable solutions. Dec. 23.
 27,932 (1907). Wack. Manganese salt for oxidation purposes. Dec. 31.

1608 (1908). Percy and Byrom. Obtaining hydrocyanic acid from waste gases. Dec. 23.

5573 (1908). Goldschmidt. *See under X.*

8768 (1908). Dieffenbach and Moldenhauer. Transformation of hydrocyanic acid into oxynitrogen compounds. Dec. 23.

10,181 (1908). Newton (Bayer und Co.). Manufacture of hydrosulphites. Dec. 23.

20,198 (1908). Willeox (Badische Anilin und Soda Fabrik). Manufacture of solid hydrosulphites. Dec. 31.

VIII.—GLASS, POTTERY, AND ENAMELS.

COMPLETE SPECIFICATIONS ACCEPTED.

- 26,189 (1907). Meakin, Ltd., and Jackson. Ovens and kilns for drying or firing ceramic wares. Dec. 31.
 6794 (1908). Gayed. Recovering china clay or china stone from decomposed granite and separating the clay, mica, and quartz. Dec. 23.
 14,841 (1908). Chem. Fabr. von Heyden. Silvering glass or other surfaces. Dec. 23.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

- 27,055. Marchetti and Marchetti. Building materials. Dec. 14.
 27,640. Bost. Manufacture of heat insulating materials. Dec. 19.
 27,902. Von Medvedsky. Production of a fireproof concrete compound. [Comprised in No. 16,118, July 29, 1908.]* Dec. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

- 13,440 (1908). Poths. Rotary kilns for burning cement. Dec. 23.
 17,119 (1908). Solomon and Austin. Compound for rendering waterproof cements and mortars. Dec. 23.

X.—METALS AND METALLURGY.

APPLICATIONS.

- 27,163. Crosley. Mineral slime-concentrating machines. Dec. 15.
 27,221. Wheatley. Metal alloy and its production. Dec. 15.
 27,353. Bloxam (Cie. des Forges de Chatillon). Pickling metals. Dec. 16.
 27,452. Stoker. Extraction of metals from their ores. Dec. 17.
 27,464. Rees, Davey, and Martin. Extraction of metals from ores. Dec. 17.
 27,498. Williams. Manufacture of wrought iron. Dec. 18.
 27,767. Arbuckle and Osborne. Separating crushed ore products or other comminuted solid matter from liquid. Dec. 21.
 27,838. Brown, Turner, and Turner. Alloying sterling silver. Dec. 22.
 27,910. De Ferranti. Coating metal articles. Dec. 22.
 28,003. Soc. Anon. Le Néo Métallurgie. Manufacture of commercially pure manganese. [Fr. Appl., Jan. 22, 1908.]* Dec. 23.
 28,081. Kurz. Manufacture of leaf metal, particularly leaf gold.* Dec. 24.
 28,172 to 28,175. Sulman, Picard, and Ballot. Concentration of ores. Dec. 24.
 28,508. Stewart. Treatment of alloys of tin and copper to separate the metals. Dec. 31.

28,509. Stewart. Treatment of alloys of tin and silver to separate the metals. Dec. 31.

28,551. Jensen (Spitz). Separating tin or other metal from waste metal, alloys, &c. Dec. 31.

COMPLETE SPECIFICATIONS ACCEPTED.

21,638 (1907). Martin. Treatment of iron or steel to prevent rust or corrosion. Dec. 23.

92 (1908). Plathner and Dorn. Coating of metals. Dec. 31.

5573 (1908). Goldschmidt. Manufacture of alloys of silicon. Dec. 23.

7211 (1908). Strange, Pim, and Matthews. Recovery of gold by the cyanide process, and other chemical processes wherein zinc is employed. Dec. 31.

7920 (1908). Peat. Apparatus for subjecting ores, shale, &c., to the action of heat in a continuous manner. Dec. 23.

8168 (1908). Messier. Basic Bessemer process. Dec. 23.

13,492 (1908). Imbert. Extraction of zinc from ores by the precipitation process. Dec. 31.

13,666 (1908). Lévy. Removing the electrolytic nickel or other metallic coating of metallic surfaces. Dec. 31.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATION.

28,147. Gibbs. Electrolytic cells. [Comprised in No. 27,830, Dec. 17, 1907.]* Dec. 24.

COMPLETE SPECIFICATIONS ACCEPTED.

14,285 (1907). Cowper-Coles. Electric hydrogen and oxygen generators. Dec. 23.

13,666 (1908). Lévy. *See under X.*

19,265 (1908). Marsh. Electric furnaces. Dec. 23.

21,741 (1908). Keller. Electric furnaces. Dec. 23.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

APPLICATIONS.

27,065. Farr. Polishing or other waxes. Dec. 14.

27,083. Buchanan. Manufacture of soap. Dec. 11.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

COMPLETE SPECIFICATION ACCEPTED.

12,517 (1908). Liebreich. Manufacture and application of oil paints. Dec. 23.

(C.)—INDIA-RUBBER.

APPLICATIONS.

27,090. Price. Preparing rubber for preservation and transportation.* Dec. 14.

27,328 Hayley (Northway). Obtaining india-rubber or caoutchouc from rubber producing machines.* Dec. 16.

27,496. Pybus and Pybus. Manufacture of rubber substitutes. Dec. 18.

27,567. Capelle. Recovery and regeneration of india-rubber, &c.* Dec. 18.

27,688. Wallace and Reynaud. Manufacture of elastic products similar to india-rubber. [Fr. Appl. Dec. 20, 1907.]* Dec. 19.

27,914. Gottschalk, Barr, and Dawson. Synthetic production of india-rubber. Dec. 22.

27,915 to 27,917. Lilley and Dawson. Synthetic production of india-rubber. Dec. 22.

28,159. Immisch. Manufacture of ebonite and vulcanite. [Comprised in No. 28,365, Dec. 24, 1907.]* Dec. 21.

28,450. Blum. Manufacture of artificial Para rubber. Dec. 30.

COMPLETE SPECIFICATION ACCEPTED.

10,731 (1908). Torrini, Hoffmann, and Benoit. Manufacture of a substitute for hard vulcanised rubber or ebonite. Dec. 23.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c. APPLICATION.

28,219. Buffum and Carter. Preparation of waterproof leather board. [U.S. Appl. Jan. 2, 1908.]* Dec. 28.

XVI.—SUGAR, STARCH, GUM, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

20,266 (1907). Hutchinson, and United Railway and Trading Co. *See under XIX.*

569 (1908). Greenwood. Manufacture of gum tragacanth. Dec. 31.

XVII.—BREWING, WINES, SPIRITS, &c.

APPLICATION.

27,956. Breker. Production of brewers' wort. [Addition to No. 25,356 of 1907.]* Dec. 23.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATIONS.

27,080. Hogarth. Treatment of air or gases for use in conditioning or improving cereals. Dec. 14.

27,218. Wesener. Apparatus for preparing gaseous mixtures for treating flour, &c. [U.S. Appl. May 14, 1908.]* Dec. 15.

27,520. Hogarth. Treatment of cereals and other alimentary substances. [Addition to No. 5155 of 1908.]* Dec. 18.

28,223. Jensen. Pasteurising or sterilising liquids.* Dec. 28.

28,241. Anyon. Treating fresh or spent hops for edible and dietetic purposes. Dec. 28.

28,507. Bloxam (Thomas). Conditioning flour. Dec. 31.

COMPLETE SPECIFICATION ACCEPTED.

8279 (1908). Snelling. Manufacture of margarine. Dec. 31.

(B.)—SANITATION; WATER PURIFICATION.

APPLICATIONS.

27,226. Ozonair, Ltd., and Joseph. Sterilisation of water by ozone or other gaseous agent. Dec. 15.

28,052. Heenan and Leask. Treatment of sewage. Dec. 24.

28,562. Guy. Bacteria beds and substances for use as bacteria medium. Dec. 31.

(C.)—DISINFECTANTS.

COMPLETE SPECIFICATION ACCEPTED.

9886 (1908). Schneider. Manufacture of disinfectants. Dec. 23.

XIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

27,123. Claviez. Manufacture of a material like paper.* Dec. 14.

27,573. Luck. Treatment of flax straw or the like for the production of cellulose. Dec. 18.

28,149. Lecoqur. *See under V.*

28,538. Ratignier, and Pervillac et Cie. Manufacture of pellicles and films. [Fr. Appl., Jan. 4, 1908.]* Dec. 31.

COMPLETE SPECIFICATIONS ACCEPTED.

20,266 (1907). Hutchinson, and United Railway and Trading Co. Treatment of bagasse. Dec. 23.

20,267 (1907). Hutchinson, and United Railway and Trading Co. Manufacture of paper and material therefor. Dec. 23.

7629 (1908). Lehner. Colouring celluloid, especially for coloured screens for photography. Dec. 23.

XX.—FINE CHEMICALS, ALKALOIDS,
ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

27,096. Knoll und Co. Manufacture of condensation mixtures from phenols and aldehydes. [Ger. Appl., July 3, 1908.]* Dec. 14.

28,011. Richter. Preparation of iodide of lecithin and bromide of lecithin.* Dec. 23.

28,434. Marks (Koch). Manufacture of ferro-albumen preparations.* Dec. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

27,735 (1907). Boult (Radiogen Ges.). Radio-active preparations. Dec. 23.

4936 (1908). Newton (Bayer und Co.). Manufacture of santalol ethers. Dec. 23.

5404 (1908). Tompkins, and Clayton Aniline Co. Manufacture of dihalogen-acetyl chloride and dihalogen-acetic acid and derivatives thereof. Dec. 31.

XXI.—PHOTOGRAPHIC MATERIALS AND
PROCESSES.

APPLICATIONS.

27,233. Mansell and Mansell. Production and reproduction of bleached images. Dec. 15.

27,686. Soc. Anon. La Photographie des Couleurs, Sury, and Bastyns. Preparation of solutions used in the bichromate gelatine process for photographic printing.* Dec. 19.

27,687. Soc. Anon. La Photographie des Couleurs, Sury, and Bastyns. Printing on paper of photographs in colour.* Dec. 19.

27,957. Lucas. Treatment of photographic sensitised gelatin films or gelatino-bromide prints for reproducing any photographic image. Dec. 23.

COMPLETE SPECIFICATIONS ACCEPTED.

7629 (1908). Lehner. *See under XIX.*

15,657 (1908). Jeannot and Bremner. Photographic toning and fixing solutions. Dec. 31.

XXII.—EXPLOSIVES, MATCHES, &c.

APPLICATIONS.

27,286. Kilburn (Rickmers). Explosives. Dec. 15.

28,012. Harris. Explosives. Dec. 23.

28,544. Andersen. Explosives.* Dec. 31.

COMPLETE SPECIFICATIONS ACCEPTED.

117 (1908). Carré. Matches. Dec. 31.

20,279 (1908). Bawden. Explosives. Dec. 23.

20,574 (1908). Farris and Jex. Blasting powder Dec. 31.

DR. MILTON L. HERSEY IN THE CHAIR.

CHEMISTRY IN ITS RELATION TO FOOD.

BY PROF. J. F. SNELL.

The sum of human knowledge on the differences between foods, and the physiological effects of these differences is still small and imperfect, and the wise man is he who is modest enough to admit the limitations of his own share of this knowledge; open minded enough to give fair consideration to rational argument, keen enough to discriminate between sound knowledge and irrational dogmatism, and strong-willed enough to shape his policy to fit the best knowledge available to him.

Though it has its physical and biological aspects it must be admitted, I think, that the diet problem is to a very great extent a chemical one. Digestion is accomplished by chemical processes, and the examination of a given commodity to determine its suitability for consumption as food must include a chemical analysis as well as a search for injurious organisms, parasitic or bacterial.

The directions in which chemistry is being applied to nutrition problems are more various than perhaps the average man realises. I wish briefly to refer to the following:

1. The determination of the relative values of foods, from the nutrition standpoint.
2. The elucidation of the processes of digestion.
3. The problem of hygienic preservation of food.
4. The detection of adulterants.

The processes of digestion are, as I have said, essentially chemical processes. The constituents of foods are: water, mineral salts, organic acids and their salts, carbohydrates, fats, and proteins.

(1) Water constitutes a large proportion of our diet. It is excreted unchanged, but the chemical processes involved in the digestion of the other nutrients are in general hydrolytic processes; in other words, digestion consists in reactions of the other nutrients with water, and it is only in the subsequent physiologico-chemical reactions, such as respiration, that the water is again liberated as such.

(2) Mineral salts. These are closely associated with the proteids, but their functions are only imperfectly understood. Like the water, the mineral salts of the diet are excreted as such, and as a diet containing a sufficient quantity of the organic nutrients is pretty certain to contain an abundant supply of the essential mineral substances, with the single exception of common salt, it is not often of practical importance to determine the quantities of mineral salts in foods; nevertheless, there are interesting questions connected with the functions of the mineral salts. Such salts are undoubtedly essential constituents of the living cell. Though our present methods of analysis do not enable us to determine just what the relationship of the mineral salts to the organic constituents is, there can be little doubt that it is an intimate one.

Forster, experimenting with dogs and pigeons with food as poor as possible in mineral substances, observed such a very marked disturbance of the functions of the organs, particularly the muscles and nerves, that death resulted in actually a shorter time than under complete starvation. Bunge, suspecting that Forster's result might be due rather to the lack of an alkali to neutralise the sulphuric and phosphoric acids formed by the oxidation of the proteids, made similar experiments with mice, and although he found that the mice lived twice as long on a diet consisting of casein, milk-fat, cane-sugar, and

sodium carbonate as on one consisting of the same foods without the sodium carbonate, he also made the remarkable observation that the life of the mice was not further prolonged by the addition of all the mineral substances of milk to the above diet, which it will have been noticed contained the organic constituents of milk, with the exception that cane-sugar was substituted for milk-sugar. A possible explanation of this result is that proteins and salts separately cannot take the place of compounds of proteins with salts. Rohmann has obtained better results than Bunge with a more varied artificial diet, having succeeded in maintaining mice on a mixture of casein, white of egg, vitellin, starch, margarine, and salts, and even in bringing up a second generation of mice on the same diet, with the addition of malt. But even with this more varied diet, which includes some foods (e.g., white of egg and malt) which are not ash-free, the mice were not normal, the second generation being undersized and incapable of producing living young.

There can be little doubt, therefore, that the mineral constituents of food are intimately associated with the organic nutrients, and very little doubt that the proteins are the particular class of nutrients with which they are combined. But as to the nature and significance of the combinations of salts and proteins we are as yet very much in the dark.

Certain tissue elements are richer in one mineral body, and others in another. Potassium compounds, for instance, occur chiefly in the form elements, sodium compounds chiefly in the fluids of the organism. For the proper functioning of the animal body, it appears to be necessary to preserve a certain balance between the sodium and potassium, and also a certain balance between the chlorides and the salts of other acids.

Bunge maintains that the specific function of the common salt, which appears to be a necessity in the diet of herbivora and of certain races and classes of men, is to supply sodium to balance the potassium, and chlorine to balance the sulphuric and phosphoric acids, supplied in excess by a vegetable diet, and cites in favour of his theory the fact that carnivora do not require salt, and that men whose diet consists largely of animal foods require less salt than those whose diet is vegetable, especially if composed largely of vegetables rich in potash, such as potatoes.

Passing over for the present the organic acids and their salts, which may be regarded as intermediate in character, we come to the three great classes of organic nutrients—carbohydrates, fats, and proteins. These are the food substances which undergo the most profound changes in the animal organism, being converted by the digestive processes into forms in which they can be absorbed into the blood or lymph, subsequently transformed into living protoplasm or stored as glycogen or as fatty tissue, and ultimately oxidised to water, carbon dioxide, and simple nitrogenous compounds, such as urea, in which simple forms they are excreted. The heat which maintains the body at its normal temperature, and the mechanical energy of muscular work are derived from the oxidation of these nutrients, and it is upon its content of the nutrients of these classes that the so-called "nutritive value" of a food is based. In one sense the nutritive value of a food is measured by the quantity of energy yielded by its oxidation in the body. A less ambiguous term for nutritive value in this sense is *fuel value*. To estimate the fuel value of a food it is therefore necessary and sufficient to determine first what proportion of the given food is actually digested and absorbed, and second, what is the heat of combustion of the food. It is here assumed that the energy yielded by the gradual oxidation characterising physiological processes is the same as that yielded by the rapid oxidation of the same food in a calorimeter; in other words, that the law of conservation of energy holds in animate as well as in inanimate nature. That this assumption is correct is indicated by the results of all the experiments made to decide the question, and

particularly by those of Atwater and his associates in a large number of experiments in which foods were on the one hand burned in a bomb calorimeter and on the other hand supplied to human subjects confined for periods of several days in a dehydrate calorimeter, provided with appliances for the collection and analysis of the respiratory products. The solid and liquid excreta were likewise collected, analysed and burned in the bomb calorimeter. Complicated as such experiments are, involving the co-operation of numerous observers and a considerable amount of apparatus—mechanical, electrical, and chemical—continued practice enabled the investigators to reduce the experimental error to less than 1 per cent., and it was found that the law of conservation of energy held strictly true up to this limit of error.

Assuming, then, the validity of the law of conservation of energy, the energy value of the food can be determined by burning a weighed portion of the food in a bomb calorimeter, and also burning in the calorimeter the excreta produced in a digestion experiment on a diet composed of the food under investigation, together with foods whose energy value has previously been determined in a similar manner.

Results somewhat less precise, but sufficiently accurate for most practical purposes are obtained by determining chemically the proportions of carbohydrates, fats, and proteins in the food, and deriving the energy values of the food by use of average figures for both the heats of combustion and the digestibilities of the nutrients of the three classes. In the case of proteins allowance has, of course, to be made for the fact that while the products of combustion in the calorimeter are water, carbon dioxide, and free nitrogen, the products of physiological oxidation are water, carbon dioxide, and the nitrogenous compounds excreted by the kidneys, chief among which is urea. It is convenient to combine the two factors—digestibility and heat of combustion—into a single value for each class of nutrients. These values are known as the "fuel values" of the nutrients, and the figures in common use are:

For Protein	1860 Cal. per lb.
" Carbohydrates	the same.
" Fats	4220 Cal. per lb.

Proteins and carbohydrates, as these figures indicate, have about equal value as heat and energy producers, while one pound of fat is the equal of about two and a quarter pounds of protein or starch.

As the term "fuel value" implies, the food has so far been regarded as bearing the same relationship to the organism that fuel bears to a furnace and engine; the food merely supplying heat and the mechanical energy that sets up and keeps the engine in motion. This analogy is useful but by no means adequate. The relationship of food to a living organism is infinitely more complex than that of fuel to the engine. One obvious difference is, that in addition to supplying heat and energy to the organism the food must provide for the continual renewal of the tissues of the organism, and in the case of young organisms, for the production of new tissue. It must serve for construction material as well as for fuel. This fact naturally complicates the estimation of the relative values of foods. For whereas all classes of nutrients may serve as fuel, proteins alone can serve as the essential construction material of cellular tissue. Consequently a fair comparison of the nutritive values of foods cannot be based on their mere fuel values. The content of protein must also be considered. Obviously no man or animal could live on a diet which did not include protein, however rich it might be in energy value. And this brings us face to face with the much controverted question: "How much protein should the diet include?"

The older dietary standards of Voit, Playfair, Atwater, &c., were based upon observations of the food actually consumed by persons in the various callings and circumstances of life. They thus assumed that the average usage of the race in respect to the total quantity of food and to the quantity of protein consumed is the best usage possible; in other words, that the average wisdom of the race is in respect to this important question the highest wisdom. Dietary standards derived in this manner by the different authorities do not differ greatly from each other,

and for purposes of discussion we may confine our attention to one of them. Voit's standard for a man of 70 kilos. (154 lb.) body weight, performing a moderate amount of muscular work, was 118 grms. of protein, 500 grms. of carbohydrates and 56 grms. of fat. The total fuel value of this dietary is 3055 cal. Per kilo. of body weight, it amounts to 43 calories of energy and 1.68 grms. of protein, of which about 1.50 grms. would be actually digested. Chittenden has of recent years called boldly into question the validity of the assumption that the average usage of the race in the matter of food consumption is correct. He maintains that the average diet, and consequently also the dietary standards based upon it, contains from two to three times as much protein as it is necessary or even wise to consume. For a man of this same body weight of 154 lb., doing the same moderate amount of work he would allow 60 grms. of protein (0.85 gm. per kilo. of body weight) or just about half that contained in the older diet standards. To give a clearer idea of what this means, I may say that 60 grms. of protein are contained in half a pound of fresh lean beef or in three-quarters of a lb. of halibut steak or in nine eggs. Of course a man adopting this dietary standard would have to use less than these quantities of meat or fish or eggs per day, because the other portions of his diet would provide part of the protein.

Chittenden would not increase this allowance of protein even for a man doing severe muscular work. He would make up the additional food necessary to such a man by an increase of the carbohydrates and fats of the diet. As to the total fuel value of the diet, he recommends a quantity just a little lower than the older dietaries—2800 calories as against the 3055 for the man at moderate work—a decrease of about 7 per cent. Chittenden's advocacy of a reduction of protein in the diet is based upon personal experience and observation, and upon the results of scientific experiments made in Yale University—some by himself, some by his colleagues. The original purpose of the experiments was to determine whether the body could maintain itself for a period of several months on a diet as low or almost as low in protein as the minimum quantity which has been found sufficient in experiments of a few days to maintain nitrogen equilibrium, i.e., to prevent a continual loss of nitrogen from the body. In experiments of six to nine months' duration upon himself and other men of his class—University professors and instructors—he found that the body could be kept in nitrogen equilibrium on a diet containing only $\frac{1}{2}$ to $\frac{2}{3}$ as much protein as Voit's standard calls for. In his own case he found his health actually improved by the change of diet, being now free from minor ailments such as headaches, which formerly caused inconvenience and discomfort, and being able to work longer without fatigue. Three years after the close of the experiments, he wrote that he was still continuing the low nitrogen diet.

Eight University athletes, formerly accustomed to a diet much higher in protein than the old standards prescribe for men doing moderate muscular work, reduced their protein to 55 grms. per day without detriment to body-weight, health, physical strength, or muscular tone. The nitrogen was gradually diminished during three months and maintained at the low level for two months longer. Twenty soldiers were maintained five months upon a diet with the same low protein content of about 55 grms. These men had daily exercises in a gymnasium, and gymnasium tests showed that at the end of the experiment they had all increased greatly in strength. The average strength of eleven of the soldiers at the beginning of the experiment was 2790, and at the end of the experiment 5100 in terms of the gymnasium tests. This remarkable increase in strength was probably due in some part to practice, for at the beginning of the experiment they were untrained, but it at least indicates that there was no failure of strength on account of the diet. The eight trained athletes showed at the beginning of their experiment a total strength test about equal to that of the soldiers at the end of theirs, but the athletes likewise gained in strength upon the low protein diet. Their initial total strength averaged 4911, their final 6612. The effect of diet on endurance was studied in a five months' experiment by Prof. Irving Fisher of Yale, nine University students serving as subjects. The men were allowed

to select their diet at will, but were to give preference to non-proteid foods, and to practise that thorough mastication of food, recommended by Mr. Horace Fletcher. At the close of the experiment the diet had fallen off about 25 per cent. in total fuel value, about 40 per cent. in total protein and over 80 per cent. in flesh foods. Six simple gymnastic endurance tests were made at the beginning, middle, and end of the experiment. We may take the first of these tests as an example. One subject could rise on his toes 300 times at the beginning of the five months' experiment, 400 times at the middle and 500 times at the end. The results with the other subjects were as follows:

	1.	2.	3.	4.	5.	6.	7.	8.	9.
Beginning	300	1007	333	69	127	1482	702	900	1263
Middle ...	400	1265	2620	65	400	—	831	1500	—
End	500	1061	3000	85	1500	1800	1263	1800	3350

Similar results were obtained with the other tests, subject 2 being the only one who did not show an improvement in practically every test.

In order that it may fulfil its functions then, the average diet must furnish a certain minimum amount of energy and a certain minimum amount of protein, the former at least (if not also the latter) varying with the muscular activity as well as with the size of the consumer. It is no doubt true also that an excessive amount of food reduces the efficiency of the body, and if Chittenden's views are correct, an excessive proportion of protein, even in a diet of correct fuel value, also tends to diminish the efficiency.

But the absolute physiological value of a food is not dependent solely upon its fuel value and its content of proteins, carbohydrates, and fats. Judged by fuel value and protein, eggs have a high nutritive value, but to those few individuals in whom they cause digestive disturbances their practical food value is evidently less than nothing. Fruits, on the other hand, supply very little fuel value and practically no protein to a diet, yet they are of great value in keeping the organs of digestion in good condition. Their virtue is believed to reside in the organic acids and salts contained in them, though probably the flavouring matters are not without influence. Dogs do not thrive on a purely vegetable diet, even if adequate in fuel value and protein content. They require that the best portion of their proteins shall be furnished in the form of flesh. So far as the speaker is aware, but little work has been done in the examination of foods for compounds of pharmacodynamic importance, but from many well-known facts such as those just cited it would appear that such compounds may play a very important part in the processes of digestion.

In the study of the chemistry of digestion, important advances have been made of recent years, but much still remains to be learned. The processes are chiefly hydrolyses—the splitting of complex carbohydrates into simpler carbohydrates; the splitting of proteins into simpler proteins, and possibly into amino acids; and the splitting of fats into glycerin and free fatty acids. All of these processes are promoted or accelerated by the influence of enzymes, secreted by the various glands connected with the alimentary canal. As to the chemical nature of the enzymes there is still much doubt, but they are believed to be themselves protein bodies. Each enzyme acts only in a medium of suitable reaction. For example, ptyalin, the starch splitting enzyme of the saliva, acts only in a neutral or alkaline medium, and the protein splitting enzyme of the gastric juice, pepsin, only in an acid medium. The most important work of digestion is done in the small intestine, into which the liver and pancreas discharge their secretions, the latter furnishing a separate ferment for each class of nutrients—trypsin for proteins, amylase for starch, invertin for sugar, and steapsin for fats.

But not only are the digestive enzymes chemical compounds, the products of chemical reactions and catalytic promoters of other chemical reactions, but the very co-ordination and regulation of the secretion of these enzymes is accomplished very largely by chemical means. It is true that the timely secretion of saliva and of gastric

juice, immediately food is ingested, are brought about through the instrumentality of the nervous system, but it has been demonstrated that the co-ordination of the secretion of the pancreatic juice with the arrival of food in the duodenum is quite independent of the nervous system, and it seems probable that the same is true of the inter-relation of some of the other chemical processes. Starling and Bayless divided all the nerves going to a loop of the small intestine; thus placing it in complete nervous isolation from the remainder of the digestive system. Yet when acid was introduced into this isolated loop it was found that a flow of pancreatic juice invariably resulted. From the mucous membrane of the duodenum and upper part of the small intestine they obtained in alcoholic solution and also in aqueous solution a substance which injected into the veins of animals evoked a copious supply of pancreatic juice. This substance, to which they give the name of secretin, appears to be secreted in the cells of the intestinal walls under the stimulation of the acid of the chyme, and to be carried by the blood to the pancreas, where it stimulates the secretion of the alkaline pancreatic juice, which, entering the duodenum, eventually neutralises the acid of the chyme, whereupon the formation of secretin ceases, until the arrival of another portion of chyme. In parallel with this pancreatic secretin, there has also been discovered in Starling's laboratory a gastric secretin. This substance secreted in the pyloric division of the stomach, which contains no oxyntic cells, causes a fresh flow of acid from the cells of the fundus or cardiac division of the stomach some 2 or 3 hours after the food is ingested.

These secretins then serve as chemical messengers from one part of the digestive system to another. Other substances of similar function play a part in physiological chemistry, and to the general class Starling applies the term hormones (from *ὁρμῶν*, I arouse).

He points out that in the simplest organisms, such as bacteria and protozoa, the only adaptations into the mechanism of which we can gain any clear insight are accomplished by chemical means, and that in the lower metazoa, such as the sponges, the co-ordination of the different cells is still wholly determined by chemical means, there being no trace of a central nervous system. The nervous system was evolved to permit of the more rapid adaptations demanded of higher organisms, but where speed is of no special advantage, the more primitive means of adaptation is still employed. The inter-relation of the hormones and the nervous system may be compared to that of the mail and the telegraph in the business world. As a means of communication in primitive communities the mail suffices. More highly organised communities demand a more rapid means of communication, and this the electric telegraph supplies. But the mail system is not abolished when the telegraph is introduced. Where speed is not essential the mail is still employed. Similarly, when in the course of animal evolution rapid communication between the organs became necessary, and a nervous system appeared to supply the means of this rapid communication; the older and slower communication by chemical means was continued where rapidity of adaptation was not essential. So in the processes of digestion we find the nervous system employed only where promptness of response is important. When food is introduced into the mouth, telegraphic messages are despatched by way of the nervous system to the salivary glands and to the stomach, and an immediate response is obtained in the secretion of saliva and gastric juice. But in the later stages of digestion, there being no such occasion for haste, messages are despatched from organ to organ by mail or messenger service, that is to say, by the hormones. Chemically, the hormones appear to be comparatively simple compounds, much simpler than the proteins and enzymes. The actual composition of any of those concerned in digestion has not been determined, but it is known that they are readily soluble in water and in alcohol, that they are not destroyed by heating to the boiling point of water, and that they are readily diffusible. The composition of two hormones employed in other physiological work than that of digestion is known and both of these are simple compounds. The two are carbonic acid,

which is produced in the muscles and stimulates the action of the respiratory organs, and adrenalin, which is secreted in the suprarenal glands and acts upon the sympathetic nervous system.

Adrenalin is a derivative of pyrocatechin, having the formula

In the direction of food preservation there still remains much for the chemist to do. The public is disposed to look with suspicion upon all the newer chemical preservatives, and no doubt a good deal of conservatism in this direction is justifiable. No new chemical should be employed as a preservative until its physiological effects have been thoroughly investigated. On the other hand, indiscriminate condemnation of chemical methods of food preservation is to be deprecated. Certain chemical preservatives, such as salt, saltpetre, and the creosote of smoke have been used for centuries, and are still used daily without question. If experience has proved these efficient and harmless it is not reasonable to suppose that some of the newer preservatives may be equally efficient and equally harmless?

In the preface to their book, "Preservatives in Food" (1906), Drs. Thresh and Porter say: "A careful study of all that has been written on this subject at home and abroad, and of inquiries made of medical practitioners, leads one to the conclusion that the dangers arising from the use of preservatives have been greatly exaggerated. It is impossible to say definitely that a single case of illness has ever been conclusively traced to the preservatives used in any article of food or drink. Preservatives have been used from time immemorial, and it would certainly be strange if with the advance of scientific knowledge better preservatives could not be discovered than those which were originally discovered by uncivilised or semi-civilised man; yet the old preservatives are permitted without question although some of them are more deleterious if not taken in moderate quantities than their modern substitutes. Many articles of food contain small quantities of proximate constituents of a poisonous character, yet no outcry is ever raised for parliamentary interference with their use, whereas if minute traces of far less potent substances are introduced for the purpose of preventing decomposition, with the consequent formation of decidedly poisonous products, prosecutions at once follow."

The active agents in the decomposition of foods are bacteria, yeasts, and moulds. Their activity is due in some instances, and possibly in all, to the enzymes which they secrete. The bacteria, either by virtue of their enzymes, or in some other manner incidental to their life processes, produce chemical changes in the food, resulting in deterioration and often in the production of very poisonous substances—ptomaines and toxins.

Preservatives are substances which either destroy the bacteria or other micro-organisms or inhibit the chemical reactions which these micro-organisms promote. One of the arguments urged against chemical preservatives is that a substance which inhibits the activity of the enzymes of the micro-organisms will *ipso facto* inhibit the activity of the digestive ferments, and so interfere with the digestion of the food. This is not necessarily the case. According to Dr. Frank Billings, of Rush Medical School, the hydrochloric acid of the stomach acts as an antiseptic, protecting the body against micro-organisms entering the stomach. Hydrochloric acid also inhibits the activity of ptyalin, the starch splitting ferment of the saliva; but far from interfering with digestion, it is an essential ingredient of gastric juices, and greatly increases the activity of the gastric ferment, pepsin. Similarly taurocholic acid, according to several investigators, is nearly as powerful an antiseptic as salicylic acid or phenol. But although it inhibits the action of the putrefying bacteria, it evidently exercises no injurious effect on the enzymes of the pancreatic juice, for taurocholic acid is a constituent of the bile, and in normal digestion is always present in the duodenum along with the pancreatic ferments

The actual observations which have been made upon the influence of such substances as borax, boric acid, and salicylic acid on the action of the digestive ferments singly have shown that the same preservative may interfere with or retard the action of one ferment, while it favours and accelerates the action of another.

It is clear then that no general condemnation of chemical preservatives—on the mere ground that they are preservatives—is valid. Each substance must rather be judged separately upon its own record. The majority of the substances used as preservatives have, when taken in sufficient quantities, decided pharmacodynamic effects. In normal health these effects are, as a rule, undesirable, and in many cases positively injurious. In pathological conditions of the body, some of them may be beneficial, others much more injurious than in normal health. It is therefore of importance to the physician to know what preservatives are contained in the foods consumed by his patients, and almost the only point concerning chemical preservatives upon which all authorities appear to be at one is the right of the consumer and of his physician to know exactly what preservatives the food contains. Laws requiring that the label should state the nature and quantity of preservative used may therefore fairly be demanded. How much farther the laws should go is a much more difficult question, and one which cannot be adequately discussed in this paper. Some attention, however, may well be given to the curious argument appearing in the Bulletin describing Dr. Wiley's experiments with salicylic acid, and repeated in his recently published book "Foods and their Adulterations"—an argument which, to his mind, wholly refutes the claim that chemical preservatives may be harmless, if the quantities taken are sufficiently small. In his own words: "The principle which is laid down is that a substance which is injurious to health when added to foods, if not a natural constituent thereof or if not added for condimental purposes, does not lose its power of injury to health because it is diluted or given in small quantities."

FIG. 1.—"Graphic chart, representing the comparative influences of foods and preservatives."—Wiley.

The argument consists in references to the accompanying diagram (Fig. 1), which shows two curves—one for foods the other for chemical preservatives, each running from the normal dose to the lethal dose. The normal dose of the foods is defined as that quantity of food which maintains a healthy adult body in equilibrium. It is arbitrarily represented on the diagram by 100. The lethal dose of food is stated to be zero. The normal dose of preservatives is assumed as zero, apparently on the ground that they are not natural constituents of foods. The lethal dose is that required to produce death, and is represented on the diagram by 100. The argument is so obscure that I find it necessary to quote the author's words: "If you add a very minute quantity of a chemical preservative, the curve representing it varies so slightly from the

horizontal base as to be impossible of measurement by ordinary means. If we follow along to the number 75, on the horizontal base, we see the deviation of the curve is sufficiently great to measure. At 50 it is still greater, at 25 still greater, while at the left of the basic line it is a maximum, extending from 0 to 100 or the lethal dose. It is easy to show by mathematical data that no matter how small the quantity of an injurious substance or preservative is, it will still produce an injurious effect, which may be infinitely small if the dose be infinitely small. It follows then as a mathematical demonstration, that any quantity of an injurious substance added to a food product must of necessity be injurious, provided it is of the nature of a drug, and the body is in a perfectly normal healthy condition."

The flaws in this so-called "mathematical demonstration" are so numerous and so obvious that one marvels that any scientific man should allow it to go forth under his name. In the first place, it is not clearly stated what the co-ordinates of the diagram are intended to represent. But since the ordinates are stated to represent quantities of preservatives one is obliged to assume that measurements along the axis of abscissæ represent degrees of injury to health—in spite of the author's intimation that injurious effects are to be measured in terms of deviation from the horizontal line. If, then, the form of the curve for preservatives be correct, the diagram would indicate that a very little preservative may produce considerable injury. But absolutely no evidence is offered that the form of the curve is that shown in the diagram. If it should happen to be that of the curve A B in Fig. 2, the

FIG. 2.—Injurious effects of preservatives possible alternatives to Wiley's curve.

addition of a small quantity of preservative would produce only an infinitesimal injury, and the matter would only become important when a certain dose of preservative was taken. In the case of many substances normally present in food the curve would obviously have the form A D E (Fig. 2), according to which the presence of either less or more than a certain quantity of the substance is injurious. It is evident that the curve for foods in Fig. 1 must have this form, since an excess of food is certainly injurious; and it is by no means clear that the same principle may not apply to some of the substances used as preservatives; that is to say, it is not clear that a preservative which in large quantities is injurious to health may not, if present in smaller quantity, be positively beneficial. Dr. Wiley's abolition of all substances naturally present in foods, and also of all substances added for condimental purposes—from the application of his "mathematical demonstration" is rather ludicrous. Why should such a mathematical principle, applying to drugs in general, fail to apply when the drug is one naturally present in the food or when it is characterised by a decided flavour? Moreover, the admission of such

exceptions to his principle would logically lead to the exclusion of the very substance in connection with whose effects the argument is advanced, for salicylic acid has been shown to occur in wines in small quantities, and to be a natural constituent of strawberries, raspberries, blackberries, currants, plums, cherries, apricots, crab-apples, and oranges.

To avoid possible misunderstanding, it may be well to explain that I am not advocating the indiscriminate use of chemical preservatives, but merely protesting against their indiscriminate condemnation. Each one must be judged upon its merits. The use of some may then be absolutely prohibited; that of others permitted for special purposes, and in quantities to be limited by law or governmental regulation, and to be clearly stated on labels.

In regard to the remaining application of chemistry to the food problem—the detection of adulterants, artificial colouring matters, &c., I can do no more than refer to the excellent service rendered the public of Canada by the Laboratory of the Inland Revenue Department—a service contributing not merely to the protection of the consumer but also to the promotion of business honesty.

Meeting held at Burlington House on Monday, January 4th, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

CINCHONAMINE AND CERTAIN OTHER RARE ALKALOIDS.

BY B. F. HOWARD, F.I.C. AND O. CHICK.

In December, 1905, the first of the present authors and F. Perry read a paper before this Society on "The Salts of the Alkaloid Cinchonamine" (this Journal, 1905, 24, 1281), in which it was pointed out that cinchonamine nitrate is exceedingly insoluble, and it was mentioned that use had been made of this peculiarity for the purpose of determining nitrates gravimetrically.

Since then the present authors have been engaged on further investigations into the nature of this alkaloid and also the alkaloids quinine, euprepine, concusconine, and cinchonine. The first part of the paper is devoted to ascertaining the extent to which qualitative tests for and quantitative estimations of nitrates can be effected by utilising the insolubility of cinchonamine nitrate. The most recently published work on this subject appears to be a paper by Arnaud in the *Annales de Chimie et de Physique*, in 1890. He states that he has used the method with satisfactory results for the estimation of nitrates in vegetable tissues, and he has also utilised it in detecting small quantities of nitric acid in effluents and mineral waters.

PART I.—The use of cinchonamine hydrochloride as a reagent for analytical purposes.

The method was first tested by the estimation of potassium nitrate in a solution of known strength, 3 grms. being made up to 300 c.c. so that 1 c.c. contained 0.01 grm. of potassium nitrate. A roughly standard solution of cinchonamine hydrochloride was prepared, 1 c.c. containing approximately 0.025 grm. of the salt, and the solution was rendered distinctly acid with hydrochloric acid, as the nitrate is least soluble in acidified solutions. It was found extremely difficult to obtain an exact balance in the volume of wash water to be used; if the crystallised cinchonamine nitrate was washed until the washings were quite free from chloride, some of the salt was dissolved and the result obtained was low; on the other hand, there was considerable risk, unless the crystal was very thoroughly washed, of including some chloride and obtaining a high result. The first four experiments failed apparently from this latter cause.

The same potassium nitrate solution, analysed by means of the nitrometer, gave the following percentages:—95, 100, 97.6, 97.6, or an average of 97.55.

In the following four estimations by the cinchonamine nitrate, the washing was continued until the filtrate gave no cloudiness with silver nitrate or nitric acid (showing absence of cinchonamine hydrochloride).

The following percentages were obtained:—98.1, 95.3, 90.3, 99.5, or an average of 97.3.

Arnaud's analysis of potassium nitrate by this method gave an average result of 98.31 per cent. The factor used for the conversion of cinchonamine nitrate into

101
359 or 0.2813.

It will be seen that this last series of results, although somewhat lower than the calculated amount, only differed from the nitrometer results by 0.24 per cent. Quite satisfactory results can be obtained if the following points are observed:—(1) A large excess of the cinchonamine solution is necessary to ensure complete precipitation; as much of the solution should be added as contains 0.6 gm. of cinchonamine hydrochloride for every 0.1 gm. of potassium nitrate to be precipitated. (2) An excess of hydrochloric acid should be added on mixing the solutions. (3) The mixture should be allowed at least twelve hours to crystallise fully. (4) Not more than about 100 c.c. of wash water should be allowed for every gram of the precipitated nitrate to be washed.

Estimation of nitrate in bismuth subnitrate.—The method cannot be applied with any degree of accuracy to this estimation on account of the unavoidable precipitation of bismuth with the cinchonamine nitrate, and the consequent loss of nitrate occurring in washing out this trace of bismuth.

The estimation of nitrate in quinine nitrate.—0.5 gm. of quinine nitrate was dissolved in 25 c.c. of hot water, 50 c.c. of the cinchonamine hydrochloride added, the mixture allowed to cool and crystallise, filtered, washed, dried, and weighed on tared filter papers. The factor used for converting cinchonamine nitrate into quinine nitrate was 405:359. Four experiments gave the following percentages: 101.9, 97.2, 100.6, and 99.0, or an average of 99.7 per cent.

In this case the method was quite satisfactory, and, moreover, by many of the recognised methods considerable difficulties would be experienced.

Mixtures of nitric and acetic acid.—A dilute solution of nitric acid containing 5 grms. of HNO_3 per litre was prepared, and mixed with different quantities of glacial acetic acid, and the cinchonamine hydrochloride solution added to precipitate the nitric acid. In each experiment 85 c.c. of the cinchonamine solution and 5 c.c. of the nitric acid solution was used and the procedure exactly as above. Four experiments gave the following percentages: 98.4, 99.6, 98.4, and 99.7, or an average of 99.03 per cent.

The presence of acetic acid did not appear to affect the solubility of the cinchonamine nitrate in any way, as although the results are somewhat low, this error is no more than one would expect from the previous estimations.

Detection of small quantities of nitric acid in the presence of glacial acetic acid.—Investigations were made with a view to ascertaining the limit of the precipitation of cinchonamine nitrate used as a qualitative test. Nitric acid and glacial acetic acid were mixed in various proportions, and the amount of nitric acid in the mixture gradually diminished until a proportion of one part in 500 of glacial acetic acid was reached. At this point the precipitate of cinchonamine nitrate obtained was only just perceptible, and this was regarded as the limit of the test. A mixture of one part of nitric acid in 1000 of acetic acid gave no indication whatever. This qualitative test was found to be far more delicate with nitric acid alone than when mixed with another acid as above. A strong precipitate was obtained on adding the cinchonamine hydrochloride solution to a nitric acid solution of 1 in 1000, while with a solution of 1 in 100,000 a perceptible crystallisation was obtained and it was found that this was the extreme limit of the test.

Estimation of nitrate in urea nitrate.—0.5 gm. of urea nitrate was dissolved in hot water and 85 c.c. of cinchonamine hydrochloride solution added, and the nitrate

allowed to crystallise and settle. Filtered, washed, dried, and weighed. Four experiments gave the following percentages: 99.5, 100.5, 99.8, 99.5, or an average of 99.82.

The above results appeared to be fairly satisfactory and it was evidently an easy method for performing an estimation which would be a difficult one by many of the recognised processes.

Quinine nitrate and quinine bismur carbamide.—The qualitative test was applied to detect varying quantities of quinine nitrate in quinine bismur carbamide, but owing to the solubility of cinchonamine nitrate in the liquor, for quantitative purposes the test proved useless.

Summary.—This method of estimating nitrates has been found to be very useful in many cases where by other methods considerable difficulty would be experienced. It was found to be quite as accurate but slower than the nitrometer method and distinctly easier of application, and it may be employed for the estimation of all nitrates, except those of the metals which give insoluble chlorides or oxychlorides. Although the cinchonamine hydrochloride is expensive as a reagent, there need be practically no loss, as all the precipitated nitrate can be recovered. It undoubtedly is a method well worthy of the notice of analysts who have to perform long and tedious experiments, to arrive at the estimation of nitrate radicles in the presence of other nitrogenous radicles of a complicated nature, for want of a practicable insoluble nitrate.

There are so many excellent qualitative tests for small quantities of nitrates that the authors would hardly venture to put it forward as a substitute for any of those in use, but here again it might be of use in cases where for any reason any of the well known tests are masked.

PART. II.—*Constitution of cinchonamine and certain other rare alkaloids.*

The only information that could be obtained in the previous investigations on the salts of this alkaloid, with regard to its constitution, was the fact that it is always found to act as a monad radicle in combination with acids, forming one salt only with halogen acids and both the normal and acid salts with sulphuric acid. The empirical formula has been determined by both Arnaud and Hesse, whose results agree very closely, to be $\text{C}_{19}\text{H}_{24}\text{N}_2\text{O}$, that of cinchonine, which has been absolutely established, being $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}$.

Raoult's freezing-point method was found to be useless for determining the molecular weight of cinchonamine, as well as of certain other alkaloids, as no satisfactory solvent could be found. The platinum-chloride method, however, was found to give very satisfactory results, the molecular weights found being 287 and 297, that calculated for $\text{C}_{19}\text{H}_{24}\text{N}_2\text{O}$ being 296. This formula can be said, therefore, to have been confirmed.

The specific rotation of cinchonamine was determined by dissolving 1 gm. of cinchonamine in alcohol, and diluting to 50 c.c., the rotation being read in a 2 d.cm. tube. The average reading was $+4^\circ 48'$, and the specific rotation, $[\alpha]_D = 120^\circ$, which agrees very closely with the value, $[\alpha]_D = +121^\circ$ given by Léger.

It was next ascertained by Zeisel's method that no methoxyl group was present in cinchonamine. The estimation was carried on as described in Meyer's "Determination of Radicles in Carbon Compounds," pp. 33—38. The potash bulbs in the first experiments were filled with red phosphorus suspended in water, but it was found that the silver iodide precipitate obtained was always dark coloured, and the precipitate on gentle heating smelt of phosphorus; so the bulbs were filled instead, in the after experiments, with a solution consisting of one part of arsenious oxide, one part of potassium carbonate, and twenty parts of water. With the bulbs so filled, the silver iodide precipitate was white, and was much more satisfactory to work with. A blank determination and an examination of quinine sulphate (the latter showing 1.016 methoxy groups per molecule) established the accuracy of the method.

Quinineine.—This alkaloid was prepared by Pasteur's method. 2 oz. of quinine bisulphate were placed in a flask in an oil bath, kept at 130°C ; $\frac{1}{2}$ oz. of water was

added, just to melt down, and then 5 c.c. of 13 per cent. sulphuric acid. The flask was stirred gently, and kept at the above temperature for four hours. The contents were then in a thick gummy state, becoming hardened on cooling. The mass was dissolved in dilute sulphuric acid, and precipitated into ether with caustic soda. The ether was evaporated off, leaving the gummy amorphous alkaloid, quinine. It was ascertained that this contained no unchanged quinine, and it was then crystallised as acid tartrate. This salt was then recrystallised. All efforts to obtain the alkaloid in a crystalline form were unsuccessful, an amorphous resinous mass being obtained in all cases. Although Hesse claims to have prepared several salts of quinine, viz., two sulphates, the hydriodide, and thiocyanate, the present authors were quite unable to obtain any other salts than the bitartrate, oxalate, and the platinochloride. With an impure alkaloid, not freed from the last traces of quinidine, which was obtained previously, several crystalline salts were apparently obtained, but these proved on examination to be merely the usual quinidine salts, and this may possibly be the cause of Hesse obtaining the crystalline salts mentioned above.

The molecular weight, determined from the platinum salt in the usual way, was found to be 328.2 (calculated for $C_{20}H_{24}N_2O_2$, = 324), and the specific rotation in chloroform solution, $[\alpha]_D^{20} = +38^\circ.40'$. This result agrees very well with that obtained by David Howard, $+39^\circ$.

The percentage of tartaric acid in the recrystallised bitartrate was determined (a) as calcium tartrate; (b) by Chapman's bismuth tartrate method (this J., 1907, 645). The percentages of tartaric acid in quinine tartrate found were (a) 26.76 per cent.; (b) 27.44 per cent., 26.90 per cent. The percentage of moisture was 12.4 per cent. Allowing for this moisture, and calculating on the formula $C_{20}H_{24}N_2O_2 \cdot C_4H_6O_6$, the theoretical result would be 27.73 per cent., which agrees fairly closely with the figures obtained experimentally.

Another portion of the tartrate was again passed through ether, and the alkaloid obtained. On neutralising this with oxalic acid, a crystallised quinine oxalate was obtained, corresponding to the formula,

In order to ascertain whether an acid oxalate of quinine existed, a portion of the above oxalate was dissolved and treated with a good excess of oxalic acid. No quinine bioxalate was obtained, even after evaporation and freezing, and there is no evidence that such a salt exists.

The presence of methoxyl groups was investigated by Zeisel's method. As the alkaloid could not be obtained in a crystalline form, the tartrate was used and very concordant results obtained, two estimations giving 0.992 and 0.997 methoxyl groups per molecule. From this it was concluded that quinine contained one methoxyl group, and was represented by the formula,

Cinchonine.—This alkaloid was prepared by a similar method mentioned by Pasteur. Cinchonine sulphate was treated with dilute sulphuric acid in the proportion of one molecule of sulphuric acid to one molecule of the salt. This mixture was treated exactly as described above in the preparation of quinine. The alkaloid was crystallised as acid tartrate, and this on recrystallisation gave figures agreeing closely with those calculated for $C_{19}H_{22}N_2O \cdot C_4H_6O_6 + H_2O$.

A portion of this tartrate was put through ether, the alkaloid obtained, and this treated with enough oxalic acid to neutralise. On analysis the oxalate salt so obtained gave figures corresponding to the formula,

The specific rotation, $[\alpha]_D^{20} = +47^\circ.13'$, was determined on the alkaloid extracted from a portion of the tartrate, and agrees very well with the figure given by David Howard, namely, 48° .

Concusconine.—The alkaloid, concusconine, is mentioned by Léger as having been extracted by Hesse from the bark of the *Remijia Purdieana*. The method he used was to extract the alkaloids from the bark with alcohol, and

to purify the concusconine according to the process mentioned below. The only salt mentioned is the sulphate, having the formula, $(C_{22}H_{26}N_2O_4)H_2SO_4$. The sample experimented with in this research was a small quantity obtained by G. E. Shaw in 1899, from the residues of cinchonamine. His method of obtaining it was on the lines described by M. Hesse. Some crude precipitated cinchonamine nitrate was boiled with acetone. The acetone extract was distilled, and the non-volatile residue shaken into ether with sodium carbonate solution. The alkaloid was washed out with sulphuric acid and then precipitated with sodium carbonate, washed, dried, and dissolved in hot alcohol. The alcoholic extract was treated with sulphuric acid, and a sulphate obtained. (The mother liquor of this was tested with hydrochloric acid for presence of chairamine and with potassium thiocyanate for presence of couchairamine, but no indication of the presence of either of these alkaloids was obtained.) This crude sulphate was purified by a series of recrystallisations from spirit. The amount of this alkaloid on which to work was so very small that no investigation could be made as to the salts which could be prepared in a crystalline state.

The molecular weight, determined by the platinochloride method, was found to be 398.8; that calculated for $C_{23}H_{26}N_2O_4$ is 394.

The specific rotation on the dry alkaloid was found to be $[\alpha]_D^{20} +19^\circ.34'$, and on the undried alkaloid, containing 1.4 per cent. of water, $20^\circ.16'$. Léger gives $+40^\circ.8'$, and it was very unfortunate that the authors were unable, for lack of material, to further investigate this difference.

The examination of concusconine for methoxy groups, was performed as described above, with the result that 1.936 methoxyl groups per molecule were found. From this we conclude that this alkaloid contains two methoxyl groups, and may be represented as,

Cupreine.—Cupreine is an alkaloid occurring in the bark of the *Remijia Pedunculata*, which was chiefly remarkable in the past as being the only bark which contained quinine and the other usual alkaloids, but not cinchonidine. For many years it has ceased to be a commercial bark, and is now almost unobtainable, and consequently the supply of cupreine is now very limited.

The platinochloride of cupreine was prepared by dissolving cupreine sulphate in dilute hydrochloric acid, and adding excess of platinum chloride solution. The yellowish amorphous precipitate was then thoroughly washed free from all impurities, with spirit, and allowed to dry. This salt was found to contain 2.50 per cent., or one molecule of moisture, and 26.44 per cent. of platinum. The formula is therefore,

Léger describes a more basic platinochloride

but the above salt was the only one obtained under various conditions.

Cupreine sulphate is said to crystallise with six molecules of water. Two samples of the commercial salt were tested for moisture, and found to contain 2.0 per cent. and 1.4 per cent. of water respectively, which does not account for even one molecule of water. These two samples were then recrystallised from water, the crystals being laid out to air-dry for about a day, when they were just hand-dry. The moisture estimations on these two samples came out at 0.8 per cent. and 0.6 per cent. of water. This seems to indicate that there is no water of crystallisation in the basic sulphate. A third lot recrystallised, air-dried, gave only 1.46 per cent. of water after four days' drying. It was found almost impossible to estimate the alkaloid in these salts with any degree of accuracy, owing to the alkaloid being soluble in alkalis, and not very soluble in ether, chloroform, etc. An estimation of the sulphate on the dry salt gave 13.69 per cent. of sulphuric acid, against 13.65 per cent. calculated for $(C_{19}H_{22}N_2O_2)_2H_2SO_4$.

The bisulphate was prepared by dissolving 6.48 grms. of basic sulphate in 15.6 c.c. of normal sulphuric acid,

evaporating to a small volume, and then allowing to crystallise. It crystallises in short thick yellow prisms. The moisture estimated in three different lots of crystals was respectively:—4.02 per cent., 4.08 per cent., and 4.20 per cent. of water. Calculated for one molecule of water, 4.22 per cent. Oudemans states that the neutral sulphate contains two molecules of water, while Hesse only found one molecule. The above results confirm Hesse's statement. 0.9598 gram. of dry salt gave 0.5170 gram. barium sulphate, which corresponds to 23.98 per cent. of sulphuric acid in the dry salt. Calculated, 24.02 per cent. The formula is therefore,

It was tried first to prepare cupreine tetra-sulphate by dissolving 3.21 grms. of neutral sulphate in 23.4 c.c. of normal sulphuric acid, but on evaporating a little, and leaving to crystallise, crystals came out which looked very much like the neutral sulphate, and on analysis, they proved to be so. A second lot was prepared, more concentrated, and with excess of sulphuric acid. This set to a solid mass of silky short needles. These were filtered, washed with a little dilute sulphuric acid, and dried over sulphuric acid in a vacuum. These crystals were rather difficult to dry, but some, given a very little wash with distilled water, dried more readily, but even these felt a little damp to the touch after two days. 1 gram. of salt lost 0.0988 gram. of moisture on drying, which corresponds to three molecules of water of crystallisation (calculated 9.64 per cent. of water). The percentage of sulphuric acid found was 38.63 per cent. The formula is, therefore,

This salt deliquesces on exposure to air.

Cupreine hydrochloride is prepared by dissolving the alkaloid in the calculated amount of hydrochloric acid (10 c.c. normal acid for each 3.1 grms. of alkaloid taken). It crystallised in small needles, coloured slightly brown. The salt contained 5.04 per cent. (1 mol.) of water, and 10.44 per cent. of hydrochloric acid on the dry salt. The formula is, therefore,

Cupreine bi-hydrochloride was prepared by dissolving the alkaloid in normal hydrochloric acid (using 20 c.c. for each 3.1 grms. of alkaloid taken), concentrating down to a small volume, and allowing to crystallise. The crystals obtained were small prisms, coloured slightly yellow. Two lots of crystals contained no water of crystallisation, and 19.09 per cent. of hydrochloric acid. Calculated for

The specific rotation of cupreine in alcohol solution was found to be $[\alpha]_D = 163^\circ 45'$. This is fairly close to the value given by Leger, viz., $-175^\circ 5'$.

The molecular weight of cupreine, ascertained by the platino-chloride method, was 314.4. This determination confirmed the formula, $C_{19}H_{22}N_2O_2$, which requires a molecular weight of 310.

This alkaloid was examined by Zeisel's method for methoxyl groups. Two experiments were performed, and in each case only a minute trace of silver iodide was obtained, so it was concluded that cupreine contains no methoxyl group.

The following table shows the results obtained compared with the four best known cinchona alkaloids:—

DISCUSSION.

The CHAIRMAN said that those who had worked on optically active substances would remember that in early times these alkaloids were the only ones which were used in resolving racemic compounds into their optically active antipodes. Mr. Howard naturally applied the base for the determination of the nitric acid, and he should like to hear how the method compared in accuracy with the employment of "nitron," which gave practically an insoluble salt with nitric acid.

Mr. DAVID HOWARD said the exact relation of the methoxy group to the active constituents of the alkaloids was a very interesting question, and he should have expected to find cupreine running in couples with quinine, which it so curiously resembled, that practically the one ready distinction between them was that the former was soluble in caustic alkali whilst quinine was not. In fact it seemed all but quinine, but not quite. The *remigias* were a puzzle to botanists, because although they had no business to contain quinine they did. The same group also gave cinchonamine and concusconine. Unfortunately the cultivation of bark was now carried to such perfection that it did not pay to bring bark over from South America, so that they did not now get the interesting curiosities they would like to. Quinine will give three sulphates, but it was extraordinarily difficult to get the double acid sulphate. A good many years ago he worked a little on these acid salts because it was the first thing which threw a light on the double ammonium in the quinine molecule. There was a possibility of four salts; but only three could be obtained readily, viz., what the French called the neutral sulphate and we called the bi-sulphate, the basic or normal, and the ordinary sulphate of commerce. If only the two could be obtained it implied a very different composition to where there was the double molecule or the linking molecule which quinine showed, whether in the ethyl compounds or in the salts.

Mr. A. C. CHAPMAN asked how cinchonamine compared with "nitron," both in respect of cost and of efficiency. The price of "nitron" was, he believed, about 10s. an ounce, but probably the cinchonamine would be more expensive. Assuming the cinchonamine nitrate to be as insoluble as the nitrate of "nitron," did the former possess any advantages over the latter? Had the authors, for example, made any experiments to ascertain whether iodides or other substances which interfered with the direct application of the "nitron" method could be disregarded when using cinchonamine? Mr. Howard had not told them in what solvents the rotatory powers of the alkaloids were determined, but, doubtless that information would be found in the paper. It was, of course, of the utmost importance that full information should be given, both on this point and also in regard to the concentration of the solutions worked with.

Mr. C. F. CROSS asked whether it had been ascertained that there was reaction between the ethereal or alcoholic nitrates, and cinchonamine salts, and if so, whether the conditions for the reaction had been arrived at?

Dr. MORGAN asked whether cinchonamine gave a precipitate with nitrous acid as well as with nitric acid?

Mr. GRANT HOOVER asked whether this cinchonamine nitrate was soluble in alcohol? He took it from the remark made that it was important to limit the amount of wash water, that it was soluble in water, and he should

Alkaloid.	Specific rotation. $[\alpha]_D$	Methoxyl group.	Molecular weight found.	Molecular weight calculated.	Formula.
CINCHONINE	+ 226°30'	None	—	294	$C_{19}H_{21}N_2(OH)$
CINCHONIDINE	- 70°	None	—	294	Do.

like to know whether the possibility of washing in alcohol had been duly considered.

Mr. F. H. CARR asked whether the presence of excessive amounts of inorganic salts influenced the precipitation of these nitrates and also whether Mr. David Howard's remark with regard to the double acid sulphate had ever been substantiated to the extent of publishing a definite analysis of the substance? He was quite aware there was much evidence of its existence, but he had not been able to produce it in a tangible form.

Mr. B. F. HOWARD, in reply, said the solvent used for the specific rotatory power was absolute alcohol. He had not ascertained how the use of cinchonamine nitrate compared practically with the "nitron" method. The present price of cinchonamine hydrochloride was about 30s. an ounce. With regard to the salts which were obtained with a sample of impure quinine, they had not attempted to apply the method to ethereal nitrates. He regretted to say he had not tried it, but there was no reason why it should not work. They had not tried the estimation in the presence of nitrites. The particular cases in which they had used the method were compounds which were difficult to analyse by other methods. Other cases which occurred to them afterwards they would certainly investigate further. The method was found to be applicable with ordinary inorganic nitrates except those which formed oxy-salts or oxychlorides, such as bismuth. In such cases, owing to the precipitation of the metallic salt along with the cinchonamine nitrate, the method could not be satisfactorily applied.

The CHAIRMAN asked why alcohol was chosen as the solvent instead of chloroform?

Mr. DAVID HOWARD said the greater number of published results on the cinchona alkaloids were made with alcohol, and that was probably the reason why the authors of this paper adopted the same method.

Meeting held at Burlington House on Monday, January 4th, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

REACTIONS BETWEEN FIBRES AND DYES.

BY W. P. DREAPER, F.I.C., F.C.S., AND A. WILSON, M.Sc.

In a previous communication (this J., 1907, 667), we have pointed out that the equilibrium established between

in a desolution system is displaced as indicated by increasing the temperature of dyeing. We now deal with another variation in dyeing caused by the presence of fibre material.

Dyes of varying constitution have been suitably applied to various fibres and their relative colour reactions noted, more particularly with reagents of an acid nature. Colour changes take place when mineral acids are added to almost all dyes. These experiments for convenience have been chiefly confined to those dyes which react with weak solutions of dyes in this manner, and are known as "indicators."

Methyl Orange on silk.—Samples of silk were dyed with 1 per cent. of this dye in neutral solution, at the boil, washed and dried. The silk was then immersed in sulphuric acid of varying concentration, the ratio of acid to fibre being kept constant and equal to 2:1 in every case. This large excess of acid reduces any secondary action between the fibre and acid in its influence on the strength of solution to a minimum. The following results were obtained:—

Methyl Orange on Silk.

Strength of acid solution.	Colour change.	
	Fibre.	Solution.
N/10	Pink	Deep pink.
N/25	Pink in 20 secs.	Deep pink.
N/50	Orange in 30 secs.	Pink.
N/75	Yellow orange	Pink.
N/100	Do.	Pink.

These observations were made immediately, and at the end of 12 hours, they were the same in both cases. A slight change in colour from the yellow shade (as originally dyed) in the case of the N/50 and N/75 solutions was probably due to the pink colour of the solutions they were saturated with, as when removed from the solution, hydroextracted and compared with a dyed silk sample moistened with distilled water, the shades were identical.

The above solutions, containing the samples, were then raised in temperature to 100° C. Part of the dye was rapidly transferred from the silk to the solution, but no further change in the shade of the remaining dye on the fibre could be detected.

Reversibility of action.—The silk from the N/10 solution was transferred to the N/100 one; the colour immediately changed to the shade of the silk sample immersed directly in that solution. Treatment with distilled water immediately restored the original shade of the dyed silk. Previous treatment at the boil with dilute acid of the silk before dyeing gave similar results. For example, a sample of silk was boiled in N/10 acid for 30 minutes, rinsed and dyed in an acid solution of Methyl Orange (red solution). The shade obtained on dyeing was a bright orange. This indicated that any acid absorbed by the fibre will not influence the shade of the dyed silk, and that even from an acid solution the silk dyes orange.

Methyl Orange on wool.—Samples of wool were dyed, under similar conditions, to the same shade as on the silk ones. The ratio of colour change was found to be practically the same as on silk, but that action took longer to complete, and the dye did not transfer itself to the solution to the same extent. The reversibility of colour change is as complete as with silk, subject to the time factor being extended. Wool transferred from N/10 acid to N/75 changed from pink to orange, but several minutes were required to complete the reaction and establish the normal result. With silk the change is almost instantaneous. Five minutes were required also to regain the normal orange shade as dyed with distilled water. Mere dilution will not give this same effect in the absence of the fibre material with this dye.

Benzopurpurine 4B on silk.—Dyed at the boil with 1 per cent. dye in neutral solution. Ratio of acid to fibre, 4:1.

Strength of sulphuric acid.	At 15° C.	Same at 100° C.
N/25	No change	No change.
N/10	Slightly bluer	Red shade restored.
N/5	Red violet	Do. partly.
N/1	Blue black	Violet.

**Reversibility of action.*—This took longer than with Methyl Orange (on the same fibre), and was complete in two hours. After 12 hours in distilled water the red shade was completely restored. In aqueous solution N/25 acid changed the colour to brown, and silk dyed in this, dyed the same shade, but rather redder. Boiling did not alter the shade of the solution.

Benzopurpurine 4B on cotton.—Dyed a similar shade in neutral solution. The effect of varying the concentration of the sulphuric acid solution was as follows:—

Benzopurpurine 4B on cotton.

Strength of sulphuric acid.	Acid/fibre.	Result on fibre.	Do. after 12 hours.
N/10	4/1	Blue	Black.
N/25	2/1	Red violet, dark	Blue.
N/50	2/1	Red violet	Navy blue.
N/100	1/1	Red violet	Chocolate.
N/500	1/1	Bluer shade	Red violet.
N/1000	1/1	Slightly bluer	Blue red.
N/5000	1/1	No change	Slightly bluer.

These figures indicate that the colour change is more pronounced than in the case of the animal fibres. A

* It is not yet known whether this restoration of colour at 100° C. is generally present with the "direct" dyes on animal fibres.

further trial indicated that with the *N* 5000 solution the colour change after 12 hours immersion was equal to that in the solution itself.

Influence of temperature.—On boiling the above samples, they all became bluer in tone. In this respect the change is in the opposite direction to that noticed with the same dye on animal fibres. This fact clearly establishes differences in the nature of the adsorption in these two cases.

Reversibility of action.—The *N*/10 sample transferred to the *N* 1000 solution slowly changed to red, but even after 48 hours standing a slight difference could be noticed between the *N* 10 and *N* 1000 samples. These figures, therefore, indicate that the relative attraction of the dye and cotton is less, and of a different order to that of dye on silk or wool. That the relative time changes do not merely indicate relative rates of diffusion of the acid in or out of the fibre substance is sufficiently evident from the rapidity of the colour changes in the reverse action on silk, and the direct action in the case of cotton. Immersion of the acid treated cotton samples in distilled water completely restored their original colour.

Benzopurpurine 4B on mercerised cotton.—The following results were obtained. Ratio of acid to fibre = 4 : 1.

Strength of acid.	Colour change.
<i>N</i> /10	Inst. change deep chocolate.
<i>N</i> /1000	Bluish after 1 hour.
<i>N</i> /5000	1 hour no change; 12 hours bluer.

Samples of ordinary cotton immersed at the same time showed similar results; but if anything, the mercerised cotton reacted in a shorter period. These results are interesting in view of the stated increased affinity of mercerised cotton for direct dyes.

Reversibility of action.—As with the cotton samples, but in a shorter time. A similar result with distilled water.

Benzopurpurine 4B on artificial silk (hydrocellulose).—*N*/5000 sulphuric acid. Distinct change after 5 minutes. *N*/10,000 sulphuric acid. Distinctly bluer after 12 hours.

The reverse actions were more rapid than with cotton, as in the case of mercerised cotton. Both these products are in a hydrated state.

Benzopurpurine 4B on wool.—Acid to fibre = 4 : 1.

Sulphuric acid solution.	Shade at 15° C.	Same, heated to 100° C.
<i>N</i> /5	Violet	Claret red.
<i>N</i> /10	Red violet	Red.
<i>N</i> /25	Claret red	Red.
<i>N</i> /50	No change	No change.

Effect of temperature.—Same as with silk. Red colour restored at the boil. Wool from a *N*/10 solution when treated at the boil recovered in shade to that of the *N* 50 one, immersed cold.

Reversibility of action.—This takes place as with silk, but, as in the case of Methyl Orange, the time taken is much longer with wool, in this case about ten times.

Litmus on silk.—Dyed in neutral solution at the boil. Effect of varying concentration of acid (sulphuric).

Silk dyed with litmus.

Strength of sulphuric acid.	Colour change on fibre.	Colour of solution.
<i>N</i> /25	Turns pink instantly	Pink instantly.
<i>N</i> /50	Turns pink in 10 secs.	Do.
<i>N</i> /100	Do. in 15 secs.	Do.
<i>N</i> /1000	Do. in 20 secs.	Do.
<i>N</i> /5000	Do. in 30 secs.	Do.
<i>N</i> /10,000	Do. in 1 minute	Do.

It was impossible to observe any difference between these samples in respect of shade. This was the same as that of the solution.

Influence of organic acids.—Silk, wool, and cotton, dyed

with Benzopurpurine 4B, gave the following results with *N*/10 acetic acid. No change with silk and wool. On cotton the shade was bluer and about equal to that obtained with *N*/50 sulphuric acid. With *N*/1 acetic acid, shade on cotton still bluer, and equal to that obtained with *N*/25 sulphuric acid. Silk and wool very slight change in colour. With Methyl Orange. On silk *N*/10 and *N*/1 acetic acid give no change. The ordinary 60 per cent. acid slowly changed the colour, while *N*/10 acetic produced a deep pink with this dye in aqueous solution. Tartaric acid reacts in a similar way.

Influence of salts on colour change.—The normal action of these bodies in cotton dyeing is specific. They increase the amount of dye adsorbed by the fibre. The following results show that the action of acids is correspondingly and in some unknown manner influenced by the bodies. Cotton samples dyed with the 4B compound were immersed in 100 c.c. of 10 per cent. solution of sodium sulphate (cryst.). Under these circumstances it required 20 c.c. of *N* 1 sulphuric acid to produce a shade equal to that produced by 1 c.c. of the same acid in 100 c.c. water. On wool and silk a similar but less pronounced result was obtained, 13 c.c. and 16 c.c. respectively of *N*/1 acid being required to produce the same shade as produced by 20 c.c. of acid added to 100 c.c. of the salt solution. With Methyl Orange corresponding results were obtained with wool and silk, wool requiring 12 c.c. and silk 15 c.c. respectively under that same conditions, as against 20 c.c. of acid in distilled water. It is remarkable that under these circumstances no further change takes place in the resulting shade on boiling, as in the absence of the salt. Experiments made with hydrochloric acid in the place of sulphuric acid indicate that similar results are obtained, showing that these results are not due to the formation on the acid sodium salt. The results with hydrochloric acid and sodium sulphate are as follows. Cotton, wool, and silk dyed with Benzopurpurine 4B, and silk and wool dyed with Methyl Orange were placed in 100 c.c. of 10 per cent. solution of sodium sulphate, plus 20 c.c. of hydrochloric acid as a standard. Similar samples were placed in 100 c.c. of water and hydrochloric acid run in until the shades were identical in the two cases.

Fibre.	Dye.	Hydrochloric acid required to equal shade in standard salt solution.
Cotton	Benzopurp. 4B.	3 c.c.
Wool	Do.	15 c.c.
Silk	Do.	16 c.c.
Wool	Meth. Orange	13 c.c.
Silk	Do.	15 c.c.

These results indicate that the restraining action of salts is present with different acids, but is not so great in the case of animal fibres. The relative action of salts in dyeing seems to correspond with these figures in its "driving on" power. This action was not noticed in solutions of the dyes. It will be remembered that one of us (Dreaper, this J., 1907, 866) has shown that solutions of such dyes lose more of their dye in the presence of soluble salts when allowed to percolate through a column of sand, than when these salts are absent. As these salts exert no restraining action on the colour changes in aqueous solution, and as the same addition increases the adsorption when mineral substances like sand replace the fibre, the action is one in which the dye must enter into closer sympathy with the fibre mass, in addition to the increased amount of dye adsorbed, as the result of any change in the solution state of the dye.

Other reactions.—The blue colour produced by acting on the 4B dye on wool is immediately changed back to red in a 10 per cent. solution of sodium sulphate. Sodium chloride behaves in a similar way to the sulphate. Sodium bisulphate "blues" cotton dyed with the 4B dye, and the colour is not restored by the further addition of the normal salt to the solution.

Basic dyes.—Similar results are obtained with basic dyes, but in this case concentrated sulphuric acid was added to 25 c.c. of the solution containing the dyed sample to produce the colour change. Wool dyed with Safranine and immersed in a solution of equal dye concentration to

that used in dyeing (0.1 gram. per litre.) gave the following reactions:—

Sulphuric acid (98%) added.	Shade of solution.	Shade of fibre.
1 c.c.	Violet	Red violet.
2 c.c.	Blue violet	Red violet.
3 c.c.	Blue violet	Violet.
6.5 c.c.	Blue	Blue violet.

Further additions of acid increased the colour change, but the solution changed more than the fibre in all cases. At 25 c.c. addition, the dye had practically all left the fibre, so the experiment was stopped at this point, the further change on the fibre from blue to green not being possible under these conditions. It may be that the blue compound has relatively small affinity for the silk, as compared with the original dye, or the dye may be associated with the acid instead of the fibre substance, and under the conditions of the experiment diffuse out of the fibre into the solution. Trials are in progress with acid colours under these conditions and in other directions, including the relative action with inorganic adsorbents.

Conclusions.—These experiments indicate that dyes like Methyl Orange and Benzopurpurine 4B are present on the fibre in a state which can hardly be defined, in terms of these colour reactions, as an indefinite one. The disturbance of the equilibrium established between the latter dye and animal fibres by variation in temperatures is also evidence in the same direction. The reversible nature of these reactions indicated a state of equilibrium as indicated. The reactions are dependent on the concentration of the acid solutions, not the ratio of acid to dye or fibre, in the case of animal fibres. With cellulose their actions follow fairly closely those of solutions. The action of salts seems to be altogether abnormal in the presence of fibre substance and dyes. This and the fact that a time factor has to be introduced in the reverse action with cotton indicates that there is some affinity between the cellulose and the dye, but that in terms of the colour changes it is of a different order to that with the animal ones. The case of litmus is, again, of a different order. The reactions between organic acids and dyes on fibres is interesting and will be followed up. It is not known whether their action is in the ratio of their activities.

In an attempt to prepare the colour acid of Methyl Orange for these experiments by decomposing the colour salt with acid, it was found that on thorough washing, the free colour acid is *orange*, and not *pink* in colour, and that the pink colour only develops in excess of acid. It is already known that unstable hydrogen chloride compounds are formed with Congo Red, which in the same way are decomposed by washing with water, and that the following compound is probably formed:—

(Schimankky. Mitt. Technol. Gewerbe-Mus., Wien. 1900, 39—40.)

Linder (this J., 1908, 485) has also suggested that association compounds are formed between acids and Metanil Yellow. The fact now established that these compounds are decomposed on dyeing, as indicated by the colour changes recorded, and that only in strong acid solutions is an equilibrium established between the dye + fibre \rightleftharpoons dye + acid, aq., is a further proof of the close relationship existing between dye and fibre. Assuming the compound with Methyl Orange, $\text{NaSO}_3.\text{C}_6\text{H}_4.\text{N}:\text{N}.\text{C}_6\text{H}_4.\text{N}(\text{CH}_3)_2$, fibre, the combination between dye and fibre is probably brought about through the $\text{N}(\text{CH}_3)_2$ group and not by the SO_3Na one, if the acid when in excess is associated with the former group. It is possible to argue that the silk (or wool) substance is associated with the dye through this group, and not through the sulphonic acid one, for silk dyes out a violet Methyl Orange solution *orange*; and the resistance of the dye on the fibre to the action of acids indicates that the group responsible for the colour change is already associated with the fibre substance. It is not even necessary to assume from these experiments that in all cases the SO_3Na group is decomposed.

Also the equilibrium established between dye + fibre \rightleftharpoons dye + acid aq., may be displaced in either direction by increased temperature according to the fibre present, as shown.

Influence of temperature on action of acids. (Benzopurpurine 4B.) Shade red.

Fibre.	Strength acid.	At 15° C.	Same heated to 100° C.
Silk ...	N/10	Charet red	Red.
Wool ...	N/25	Charet red	Red.
Cotton ...	N/25	Red violet (dark)	Blue.

In the obscure reaction of assistants in dyeing, and more particularly in the case of acids, and assuming the presence of the above associated compounds, there is evidence that these compounds are adsorbed more easily than the dye itself, even if they are decomposed in the process. The need of an excess of acid in dyeing over that necessary to set free the colour acid may be indicated in this way.

To sum up, the evidence brought forward in a series of papers dealing with dyeing reactions, apart from the work of other investigators, is as follows. The abnormal reactions of ingrain colours, and the refusal of some developers to react in the presence of animal fibres (Dreaper, this J., 1894, 96), the variation in desolution effects due to dyeing conditions (Dreaper and Wilson, this J., 1906, 375); the abnormal reaction between picric acid and fibres under a vacuum (Dreaper and Stokes, J. Soc. Dyers and Col., 1909, 10), when taken in conjunction with the present results, confirm the extreme complexity of the reactions involved in dyeing, and to a certain extent indicate their nature.

Surface concentration, as predicted by one of us (Dreaper, this J., 1905, 223), does take place from dye solutions, complete extractions taking place from these when they slowly percolate through a column of sand (Dreaper, this J., 1907, 866). There is no reason why a similar concentration should not take place in the fibre area. It is equally clear, however, that in some cases the above results do not agree with the view, that the dye is present in a mere state of colloid slime, held mechanically in the fibre area. If these reactions are the normal ones of reacting colloids in pseudo-solutions they throw further light on the behaviour of these little understood compounds.

The above reactions with Methyl Orange are also of interest from the point of the use of these dyes as indicators. The fact that the silk or wool samples turned pink do not change back to orange on drying is also interesting.

DISCUSSION.

Mr. J. W. LOYBOND asked if the authors noticed any difference in the change of character in the solution, not corresponding, but having a relation to the changes of the fibre in No. 1 diagram, and in No. 2 diagram. In the action of Benzopurpurine 4B on silk he noticed in the third line there was a change from one colour division of the spectrum to the other, namely, that the colour was transferred from the blue side of the violet to the red and then back again to the blue accompanied apparently by a considerable loss of colour. This was so unusual that it suggested the possibility of a change in character quite different from the first change. Then in the other diagram, had it been noticed whether there was any change in colour depth in the fibre or in the solution having relation to the difference of time?

Mr. C. F. CROSS asked whether it was a fair interpretation of results to take them as consistent with the view that the dyeing result was analogous to a double salt formation, modified by interactions of the active groups of dyestuff and fibre substances?

Dr. G. T. MORGAN said that the experiments showed that it was unsafe to assume that either a mechanical, physical, or chemical theory alone was sufficient for all the facts of experience. They had, in the speaker's opinion, demonstrated not merely that the animal fibres could fix successively acid and dye,

but could hold these reagents apart in the molecules of the final complex compounds formed within the material. Even in the case of cellulose, the most inert of the three fibres examined, there was evidence of chemical combination. The acetylcellulose exhibited at the last meeting of the Society by Mr. Cross might be mentioned in this connection, for this material, although retaining the physical structure of the original cotton, nevertheless had but little affinity for the substantive colours which dye ordinary cotton directly. A chemical alteration of the substance, namely, the replacement of hydroxyl by acetoxy, leads, in this instance, to a marked difference in the behaviour of the fibre towards the dye.

Mr. J. F. BRIGGS agreed with Dr. Morgan that in investigating a dyestuff account ought to be taken not only of its constitution, but of that of the substance dyed, and the effect that any particular liquid might have. Some of the cellulose esters would dye in alcoholic solutions, but would not take the dye from an aqueous solution, and that showed that the liquid played a chemical part just as much as the fibre or the dye itself. These tables seemed to show that the fibres acted as a sort of insoluble alkali or base, and in connection with that, Ditz had recently pointed out that an insoluble acid produced no change in an aqueous solution of Methyl Orange, but that on adding sodium chloride to the Methyl Orange, the presence of the salt developed the acid reaction of the insoluble acid. He suggested that Mr. Dreaper's observations on the effect of sodium sulphate seemed to indicate that the salt made the insoluble alkalinity of the fibres more pronounced, *i.e.*, it required more acid to produce the colour changes with sodium sulphate than without it, and this might be described as a similar but converse action to that observed by Ditz with insoluble acids.

Mr. CLAYTON BEADLE said one point brought out in this paper was that dyestuffs established a sort of equilibrium between the solution and the substance to be dyed. In regard to cellulose, it appeared to him that taking an aqueous solution, the cellulose altered its affinity towards dyestuffs depending on the amount of water or the hydration the cellulose underwent. Mercerised cellulose took up a considerable amount of water. If this was dried after removal of the alkali it became dehydrated and on placing the mercerised cellulose again in water it did not take up so much as before drying. He had noticed that the affinity towards dyestuffs was greater in proportion to the amount of hydration of the cellulose, and there are many instances showing that the activity of cellulose towards dyestuffs was largely determined by the amount of its hydration.

Dr. H. P. SEYENS asked if Mr. Dreaper had examined the salts of any of these solutions by the spectrum. He believed an examination of the absorption spectrum would throw a great deal of light upon the coloured changes, especially when the colour ran from one end of the spectrum to the other.

Dr. E. FEILMANN said one rather interesting fact was brought out in this paper to which perhaps not sufficient attention had been directed hitherto, owing partly to technical considerations; namely, that dyeing was essentially a time phenomenon. They probably all had their own views on these matters, and those who were rather inclined to emphasise the colloidal nature of the phenomenon knew that in all colloidal changes the question of time, and in fact the whole previous history of the reacting substance, was one of very great importance. One aspect of the paper struck him as interesting, *viz.*, whether the colour changes might not be partly due to an alteration in the size of the particles of the dyestuff both in the fibre and in the dye-bath. If to an ordinary pseudo-solution of an inorganic substance very small amounts of acid were added with a certain amount of the electrolyte coagulation was not necessarily complete, but the small discrete particles became larger, and by suitably reducing the concentration of the electrolyte, in a good many cases the particles became smaller again; they seemed to disintegrate. In such cases, with a comparatively coarse pseudo-solution such as could be obtained with finely divided metals, a distinct change was noticeable in the apparent shade of the solution. It was possible that some

such changes might go on and alter the colour of the fibre and the solution to an appreciable extent.

Mr. DREAPER said it was impossible to deal fully with the many questions which had been raised. In the colour changes dealt with in these experiments, they had been unable to deal fully with the question as to their nature. This would be his reply to the question with regard to the absorption spectrum. He could hardly answer Mr. Cross's question in a few sentences, but he thought there might be some double salt union, as suggested. The relative colour changes which took place on fibre and in the solution in these experiments might be taken to support such a view. He agreed with Dr. Morgan in thinking that there must be a blending of all three ways of explaining the nature of dyeing. The case of acetylcellulose resisting the dyeing action, he believed the action was due to its water-resisting properties. Mr. Briggs' remarks about alcoholic solutions were certainly interesting and some very curious results had been obtained generally by dyeing in different solutions besides water. As to the time phenomenon the retarding action was more pronounced in the case of wool than in silk, and was hardly present at all in cotton, but as to exactly what these results meant in terms of colloidal activity, he would hardly like to speculate on the evidence before them.

Meeting held at Burlington House, on Monday, January 4th, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

A PHYSICO-CHEMICAL METHOD FOR COMPARING THE ANTISEPTIC VALUE OF DISINFECTANTS.

BY S. B. SCHRYVER, D.S.C., PH.D., AND R. LESSING, PH.D.

Various methods have been proposed for determining the antiseptic value of the numerous products, proprietary and others, which have in recent years been employed for the purposes of disinfection. The best known, perhaps, are the "thread method" of Koch, the "garnet method" of Krönig and Paul, and the method which has been extensively employed in this country, of Rideal and Walker. A general account of these has been recently given in a valuable work by Miss Harriet Chick, (1) who has investigated in some detail the laws of disinfection.

In the Rideal-Walker method, definite small amounts of broth-culture of the same species and age are added to a constant volume of a disinfectant solution. A series of trials are made with varying concentrations of the disinfectant to be tested, and of pure phenol under similar conditions, and the relative concentrations necessary to complete germicidal action within equal periods of time are thereby determined. The ratio of the reciprocals of these concentrations was termed by Rideal and Walker the "carbolic acid co-efficient," and was regarded by them as the standard of disinfecting power. Various objections have been made to this method, chiefly on the ground that the actual test for disinfection is carried out in the absence of organic matter other than that present in the disinfectant and the minute amount introduced by the bacterial culture, and the conditions of the trial are not, therefore, entirely analogous to those under which antiseptics are ordinarily employed. Somerville and Walker have endeavoured to remedy this defect by carrying out the disinfecting test in the presence of known quantities of added organic matter, such as protein and starch, and have in some cases obtained widely different numbers for the carbolic acid coefficient.

The addition of organic matter can act in different ways with different disinfectants. In some cases, as, for example, in that of permanganate, the disinfectant can be directly destroyed by acting as an oxidiser to the organic matter; in other cases, again, the disinfectant can be dissolved by the organic matter and thus removed from solution and its sphere of activity, an action which is conceivable when disinfection is carried out in the presence of fats by substances soluble in organic solvents. A still more complicated case is that where adsorption of the disinfectant by the organic matter takes place, a process which probably accounts for the behaviour of certain antiseptics recently investigated by Ehrlich

and Bechhold (2). In all such cases the addition of organic matter would considerably lower the carboic acid coefficient. Nor need such a lowering of the coefficient always indicate a diminished practical value. It is not impossible, for example, that the disinfectant might be adsorbed by solid matter: if the latter were the material required to be disinfected, it would, after the separation from the surrounding liquid matter, contain a higher percentage of the disinfectant than the latter, in which case a lowering of the carboic acid coefficient by the addition of organic matter should denote an increased practical efficiency.

One more action of organic matter deserves consideration. Many of the more recently introduced disinfectants are emulsions, and it is generally admitted that their efficiency depends to a great extent on the degree of emulsification, for the addition of organic matter might either accelerate or inhibit the rate of de-emulsification and thus, by a purely physical method, either decrease or increase the practical value.

Enough has been said to indicate the great complexity of the problem due to the introduction of organic matter, and as the mere germicidal value as indicated by the various methods already mentioned is regarded as an insufficient test of the practical efficiency of an antiseptic, the authors have ventured to suggest that a new method, described in the following pages, may throw some further light on this vexed question.

Principle of the method.—The rate of chemical change produced in a substrate by bacterial infection may be regarded as a measure of the vigour of the growth. By introducing substances inimical to the bacteria, the rate of growth may be inhibited or even entirely impeded. The principle of the method herein described depends essentially upon the measurement of inhibition produced when varying quantities of an antiseptic are added to an infected medium, and comparing these quantities with the amounts of phenol or any other standard disinfectant which will produce the same result.

Of the chemical changes produced by bacteria, those of protein degradation or conversion of dextrose into lactic acid both lend themselves to chemical measurement. A measurement of the rate of putrefactive change in a gelatin-peptone substrate has been already carried out by one of the authors of this paper (Schryver, Report No. 1, Inspector of Foods' Department, Local Government Board). In this case a meat essence was infected with putrefying liver, and the nitrogen determined in the filtrate from the precipitate produced by adding a given volume of tannic acid mixture to a given volume of the medium removed from the main bulk after different intervals of incubation. This purely chemical method involves a relatively large amount of labour and is impracticable, when it is necessary to measure the rate of change which takes place in different concentrations of an antiseptic, owing to the large number of analyses involved. Fortunately, the chemical change in the case of protein degradation at any rate, closely responds to certain changes in the physical properties which can be readily and accurately measured, and in the following investigations the electrolytic conductivity has been taken as the index of chemical change. This physical property has already been employed for studying protein changes, notably by Sjöqvist,⁽³⁾ Oker-Blom,⁽⁴⁾ and Bayliss,⁽⁵⁾ the last-named of whom studied by this method the chemical dynamics of tryptic digestion.

The medium used in the following experiments has been either gelatin-peptone or sodium caseinogen-peptone mixture containing about 5 per cent. of gelatin or sodium caseinogenate (*i.e.*, caseinogen dissolved in the requisite amount of sodium hydroxide) and 1 per cent. Witte's peptone. In all cases a mixed infection by faeces has been employed. Such an infection was found to produce a much more rapid change in the substrate than is produced by the inoculation with a pure strain, probably owing to the fact that the action of the different species is specific, some degrading the protein to albumoses or proteoses, others acting only on these latter bodies, and others again only on amino-acids, as shown by Nawiasky⁽⁶⁾. A similar method of infection has also been employed by M. Wynter Blyth⁽⁷⁾.

Apparatus.—The ordinary method as described in text-books was employed. The only part of the apparatus which requires any special mention is that of the electrodes of which a sketch is appended (Fig. 1). They consist

FIG. 1.

of platinum plates coated with platinum black, made of fairly stiff pieces of metal 10 mm. square and placed 20 mm. apart. These were fused into glass tubes of the shape indicated which were filled with mercury into which the wires connecting the electrodes with the remainder of the apparatus could be placed. The tubes were fitted by means of india-rubber into a glass collar which, resting on the rim of the test tube containing the liquid the conductivity of which was to be measured, enabled the electrodes to be adjusted in a convenient position. One pair of electrodes constructed in this manner could be used for an unlimited number of determinations, as they could be readily moved from one test tube to another. The test tubes employed measured 30 by 95 mm., and were placed for the purpose of the determinations in a constant temperature bath heated to 37° C. Throughout this research all the readings were taken at this temperature. An expensive resistance box is not required; when electrodes of the character and size described are employed and the solutions infected contain 5 per cent. gelatin or caseinogenate and 1 per cent. peptone a single coil of approximately 100 ohms will serve quite well as a counterbalancing resistance. This was used in all the experiments described, the initial resistance of the liquids varying generally only between 100 and 200 ohms.

The relationship between electrolytic conductivity and protein degradation.—This relationship has already been determined by Bayliss in his investigations on the action of trypsin on caseinogen, where he found that the curves representing the conductivity of the caseinogen solution in different stages of digestion and the nitrogen in the filtrate from the tannic acid precipitation were very similar in form. The following experiment gives a typical example of a putrefactive change, in which both the conductivity of the solution and the nitrogen in the tannic acid filtrate were determined.

A sterile solution containing 5 grms. of gelatin and 1 gm. of peptone in 100 c.c. of liquid was infected with faeces, and incubated at 37° C. It was thoroughly shaken up during the earlier period of incubation to ensure uniform infection throughout the fluid. At the commencement of incubation and at successive periods of 24 hours 10 c.c. of the mixture were pipetted out and weighed and then diluted to 100 c.c. the weighing bottle was

washed out with 10 c.c. of water and 40 c.c. of tannic acid mixture was then added.*

The whole was then made up to 200 c.c. and filtered, and the nitrogen determined in 150 c.c. of the filtrate. The results are indicated in Table I., and Fig. 11.

TABLE I.

Time of incubation.	Mg. nitrogen in filtrate.	Resistance in Ohms.	Conductivity in Gemmos.
Beginning	11.3	156.6	6.39
1 day	13.0	125.7	7.96

3 days	43.9	39.0	25.64
4 days	56.0	30.0	33.33
6 days	89.3	18.3	56.64

FIG. 2.

The effect of the antiseptic on the rate of change.—The following experiment was carried out to determine the influence of varying quantities of antiseptic on the form of the conductivity curve. A solution of 5 per cent. gelatin and 1 per cent. peptone was infected in bulk with faeces and warmed for a short time at 37° C. with repeated shaking to ensure uniform infection. Portions of 90 c.c. of the infected liquid were placed in six sterile flasks to which were added respectively 10, 5, 2, 1, and 0.5 c.c. of a 5 per cent. phenol solution which had been standardised by the Messinger-Vortmann method; to the sixth flask no disinfectant at all was added. In all cases the total bulk of the fluid was made up to 100 c.c. with sterilised water. All the portions were incubated at 37° C. and quantities of about 15 c.c. were taken out at intervals and their conductivity determined. They were placed in series in the test tubes already described in the constant temperature bath, the sample from the portion containing no disinfectant being at one end of the series and that containing the most disinfectant being at the other. Sufficient time must be allowed for the electrodes to

* Tannic acid 100 grms., sodium acetate 25 grms., sodium chloride 75 grms., glacial acetic acid 50 grms., water 1000 grms.

attain the full temperature of the surrounding liquid, 10 to 15 minutes is generally required in the case of the first tube. They do not cool much when moved to the following tubes. Some of the slight discrepancies in the tables are due to the fact that sufficient time was not allowed for the electrodes to reach the requisite temperature.

The results of these experiments are recorded in Table II.

TABLE II.

Per cent. phenol.	Beginning.	28.5 hrs.	44 hrs.	53 hrs.	69 hrs.	77 hrs.	93 hrs.
0.00 ...	220	150.0	54.2	37.9	30.0	28.5	26.0
0.025 ...	220	170.3	103.7	52.0	33.0	—	33.0
0.05 ...	220	184.9	180.1	91.2	62.3	61.0	40.0
0.10 ...	220	220	218.0	198.5	210.0	220	—
0.25 ...	220	—	—	No change	—	—	—
0.50 ...	220	—	—	No change	—	—	—

Influence of varying concentration of phenols on gelatin-peptone mixture. Numbers indicate resistance in Ohms.

From this table it will be seen that no putrefaction takes place within four days, where the concentration of the phenol reaches 0.1 per cent. A concentration of 0.05 per cent. is however insufficient to altogether stop putrefaction within this period, although it considerably impedes it. The results are graphically plotted in Fig. 3.

FIG. 3.

The actual bridge readings are appended in this table (Table III.) to denote the magnitude of the measured change.

Bridge-readings corresponding to resistances in Table II.

The influence of the activity of the infecting growth on the rate of change.—In the above experiments the substrate was directly infected with fresh faeces. In the following, 100 c.c. of the gelatin-peptone mixture was infected with fresh faeces. The conductivity of the solution was determined at definite intervals in different stages of the change, at which 1 c.c. of the mixture was removed by

a sterile pipette and used to inoculate fresh quantities, each of 100 c.c., of a similar gelatin-peptone solution. The rate of change was then determined in each of these sub-cultures. Furthermore, when the determinations indicated a rapid change in the conductivity of the originally infected liquid (*i.e.*, after 40 hours' incubation) fresh portions, each of 100 c.c., were reinfected from it with respectively 1, 3, and 5 c.c. of liquid, in order to determine the influence of the volume of the infecting fluid upon the rate of change.

Influence of age of culture on rate of change, when making sub-cultures. Resistances in Ohms.

From the above table it will be noticed that if the sub-infections be made from the original infected liquid after a short time of incubation, and during the period in which only slow changes are taking place, the sub-infected liquid will only change with comparative slowness, more slowly, in fact, than the original infection. If on the other hand, the sub-infection be made from the original during a period of rapid change, the sub-infected liquid will also undergo a very rapid change. Moreover, a period of maximum rate of change appears to be reached, for sub-infections made during the period of very rapid change, showed that the rate of degradation in the sub-infected liquid was practically independent

of the amount of substance used for the purpose of inoculation. Thus, in experiments 4, 5, and 6, 1, 3, and 5 c.c. respectively of the originally infected liquid were used for the purposes of the sub-culture. In all cases the change of conductivity of the sub-infected liquid took place at practically the same rate. A somewhat similar result has been obtained by Adrian Brown by a purely biological method, in investigating the rate of growth of yeast cells. He has shown here that a maximum rate of growth can be attained which cannot be surpassed by using larger numbers of cells for inoculation of the medium. A few of the above results are plotted on the accompanying curve. (Fig. 4.)

An experiment was also made to determine whether the results are due to bacterial growth with the consequent production of endogenous enzymes or to exogenous excreted enzymes, which latter could act even after the death of the bacteria. For this purpose, some of the original growth was incubated for about 40 hours. It

was then filtered into a sterile flask through a sterilised Berkefeld filter. The conductivity of the filtrate was then determined, and it was then incubated for several days. It showed no change of conductivity during this period, the resistance remaining constant the whole time. Neither did a Mett gelatin tube, when placed in the liquid, undergo any change. These experiments indicate the absence of any exogenous proteolytic enzyme in the liquid. Several experiments similar to the above, both with gelatin and caseinogen media have been carried out, which yielded substantially the same results. These indicate that by means of the method interesting data as to the life history of bacteria might be obtained. It is also suggested that a subinfection made at the period when the maximum rate of change is produced might

FIG. 4.

be conveniently employed for testing the efficiency of antiseptics.

Comparison of disinfectants.—In the following experiments, six different disinfectants were employed, viz., mercuric chloride, formaldehyde, and phenol, and three proprietary disinfectants A, B, and C. Altogether four series of experiments were carried out with these disinfectants, two with the gelatin-peptone mixture and two with sodium caseinogen-peptone mixture. In Series I, small quantities of the media were emulsified

mercuric chloride practically no change had taken place in the conductivity, even in the most dilute solution of disinfectant. Phenol was the weakest, disinfectant A, was appreciably more effective, whereas B, and C, were more effective than A, C being the most efficient of all. In the accompanying curve, the relative amounts of disinfectant are plotted as abscissae and the differences between the initial and final resistances as ordinates. The relative efficiencies are thereby indicated at a glance. The actual results are recorded in Table V.

with a small amount of human faeces, and the emulsion filtered through a platinum sieve to separate the coarser particles. The filtrate was added to a large quantity of the medium with which the emulsion was made. The whole was then incubated for a short time with constant shaking, so as to obtain a homogeneous mixture, and quantities of 20 c.c. were pipetted out into sterile vessels. The pipette used for this purpose was connected through rubber tubing by means of a two-way tap, with a vacuum pump or with the outer air, in both cases through a sterile plug of cotton wool. In each series five mixtures were made with five different quantities of the antiseptics, viz., with 5, 2, 1, 0.5 and 0.25 c.c. of a 2.5 per cent. solution of each disinfectant and 20 c.c. of infected medium. In every case the total bulk of the liquid was made up to 25 c.c. with sterile water. The degree of putrefaction was consequently determined in mixtures containing 0.5, 0.2, 0.1, 0.05 and 0.025 per cent. of each disinfectant.

In Series II, the experiments were exactly similar to those in Series I, with the exception that, instead of infecting the medium directly with faeces, it was inoculated with some of the same medium which had already undergone considerable putrefaction. Thus, the gelatin-peptone mixture (6 per cent. gelatin, 1.5 per cent. peptone) with original resistance 151.9 ohms, was infected with faeces and allowed to putrefy for 48 hours. Its resistance had then sunk to 34.6 Ohms. A caseinogen-peptone mixture (6.0 per cent. caseinogen, 1.5 per cent. peptone) with original resistance 130.0 ohms was allowed to putrefy for the same time also after faecal contamination. Its resistance was also lowered to 34.6 ohms. Small quantities of the former putrefying mixture were added to a large quantity of gelatin-peptone solution (6.0 per cent. gelatin, 1.5 per cent. peptone) and small quantities of the latter were added to large quantities of the caseinogen-peptone solution (6.0 per cent. caseinogen, 1.5 per cent. peptone). In Series I, the tests for disinfecting value were carried out in slowly putrefying medium and in Series II, in a rapidly putrefying medium. After five days' incubation the resistance in each experiment was determined. In all four sets, substantially the same results were obtained. In the case of formaldehyde and

Comparison of influence of different antiseptics on amount of putrefactive change after 5 days' incubation of mixtures. Resistances in Ohms. Italicised figures represent the initial resistances, when determined, before incubation of mixtures.

Caseinogen solutions undergo a small change on incubation, even in the absence of putrefaction; the alteration in conductivity, is, however, small, when compared with the changes produced by putrefaction, and can be readily controlled by carrying out a blank experiment in the presence of toluol. For this reason, the gelatin-peptone mixture is to be preferred when testing the efficiency of antiseptics. In this latter medium, the changes are small. It will be noticed that, as would be expected, the addition of mercuric chloride diminishes the resistance of the substrate; formalin, on the other hand, increases it, owing probably, to its capacity to enter into chemical combination with amino-derivatives. The disinfectants themselves, also exert sometimes small changes when present in large quantities, owing to their acid or basic characters. In no case however can such changes be mistaken for a putrefactive alteration.

Conclusions.—Many problems with regard to bacterial growth and disinfection are suggested by the above recorded experiments and the present communication must be regarded as of a preliminary nature.

The factors concerned in the process of disinfection are so complex that the authors have for the present avoided the use of the word "standardisation" in their description of the suggested methods. Nor have they attempted, so far, to express any numerical relationship when comparing the antiseptic value of the different disinfectants examined. There are however various methods by means of which such a relationship might be fixed: the most feasible would be to determine the relative quantities of the disinfectant which are just necessary to entirely inhibit putrefaction during a given interval. Thus on reference to Fig. 5 it would be noticed that no change was produced in the substrate when phenol was in the concentration of 5 parts per mille, although a considerable amount took place when

FIG. 5.

2.5 parts per mille were present. The amount necessary for total inhibition lies somewhere between these limits. In disinfectant C, these limits lie between 1.0 and 0.5 parts per mille. By taking a larger number of dilutions these limits can be considerably narrowed and the relative amounts just necessary to inhibit putrefaction within a given time ascertained. It is proposed to continue the investigations on this subject.

The method suggested has many advantages, notably the small amount of time and labour involved and the simplicity of manipulation. It is furthermore adaptable to a large number of conditions, varying substrates and disinfectants in different physical forms, such as powders, emulsions or organic solvents. It is hoped that this wide range of applicability will render the method acceptable to those engaged in the examination of antiseptics.

DISCUSSION.

The CHAIRMAN said that the authors had only applied themselves to proteids. He should have liked to hear something with regard to the fate of the fats, as he had occasion to study somewhat extensively the constitution of sewage fats. It was well known that the neutral fats were hydrolysed by the bacteria in the sewage into free fatty acids and glycerol. The fatty matter of the sewage fats contained considerable quantities of coprosterol which seemed to be the degradation product to which both cholesterol and phytosterol are broken down in the alimentary canal.

Dr. S. DREYFUS asked if the authors had made any comparative tests as to this method and that of Rideal and Walker, and how had the results compared? It seemed to him at first sight that this method of measuring resistance was a little complicated, but he might change his opinion when he became better acquainted with it.

Dr. SOMMERVILLE said an interesting point arose as to whether or not the enzymes of the lower bowel continued their action, when separated from the bacteria which produced them; or whether there might not be such a quantity of enzymes in the ordinary intestinal contents as some were disposed to believe. He had been engaged on the bacteriology of the lower intestinal tract for some years, and he thought no section of modern medicine was fuller of interest to the chemist, to the physiologist, to the pathologist, and to the practising physician. They owed a great deal to Dr. Herter of Columbia University for the work he had done on the flora of the upper and lower intestinal tracts, and if it should prove true that there was a physiological sup-

pression of enzymes in the lower tract he would consider that Drs. Schryver and Lessing had thrown light on an interesting subject.

Dr. S. RIDEAL said the authors proposed to test the antiseptic value of a chemical substance by the amount of chemical change after bacterial infection brought about in its presence as compared with the change in its absence; in other words, it was a method which was eminently applicable to the determination of the behaviour of preservatives—of antiseptics as distinguished from germicides or disinfectants—and would throw light on the changes which took place, for example, when food was kept under different circumstances. That class of work could be measured by this method provided the resistance changes were comparable one with another. But they had not sufficient data at present, as the authors would admit, to ascertain, for example, whether their solution—3 per cent. gelatin and 1 per cent. peptone—had a uniform resistance, or the variation of experimental error in the resistance of such a solution when it had undergone no change at the blood heat temperature. The viscosity of glue or gelatin solutions of equal percentage composition varied considerably, and he thought the same would be true of conductivity. The changes which took place went over a long period, before you got the curve shown, and they would like to know more about the breaks in the curve, which evidently took place from day to day. For example, small quantities of salt introduced into the solution with the disinfectant to be tested would influence the original conductivity of the solution and also the shape of the curve during the period under observation. All these factors had to be considered before one could venture to put forward this as a practical method for testing disinfectants. One would think it would be better to measure the amount of change by some chemical method rather than a physical method, and he had always felt a doubt in his own mind as to what a difference in the conductivity of a solution actually meant. It was all very well to say it meant the breaking down of a mixture, but the peptone was already broken down to start with, and that had increased the conductivity of the medium initially. He supposed the peptone was introduced in order to enable the gelatin to conduct electricity to start with. Then again they took faeces of unknown origin, containing a number of organisms of different kinds, and had shown that the sequence in the breaking down of the gelatin through the albumenoses and amino acids was brought about by a variety of organisms, working one after the other, some symbiotically, but most of them by sequence; and it was therefore very difficult to ensure that a given sample of faeces contained the right proportion of organisms to degrade the gelatin and peptone in the way suggested. The absence of enzymes was very astonishing, in the ordinary liquefaction of gelatin by *B. liquefaciens*, *fluorescens*, and by *B. prodigiosus*, he had found an enzyme was produced (Rideal and Orchard, Analyst, 1897). The method associated with his own name and Mr. Walker's had never been put forward as one for determining the way in which a disinfectant was going to do its work, but simply as a way of enabling the manufacturer and the purchaser to see that they were getting an article according to sample—a commercial method which would enable buyer and seller to judge whether the article was according to specification. In every case, the way in which a disinfectant, after it had been sold, was going to be used, its strength, and whether it was to be used in the presence of organic matter or not, and whether for sterilising water or for disinfecting solid faeces, containing fat or urine or liquid faeces like cholera stools in which there was no fat, or the fat was already emulsified—all that had to be judged by the medical officer in charge of the public health of the district or house or patient. Every case was different, and must be judged locally by the expert in charge. He believed it was impossible for any single test to be devised which would meet all cases of practical disinfection.

Dr. BOUSFIELD said the question of standardising disinfectants was essentially a twofold one. Speaking as a bacteriologist, he had no hesitation in saying that

the academical test and the practical test were essentially different things, and in his opinion the two could never be satisfactorily brought together. It was one thing to do as Rideal and Walker had done, devise a method which gave a certain result in the presence of a small definite quantity of organic matter, and quite another thing to take a pure culture and determine what effect could be produced upon that. Then again that depended upon the question of the resistance of the particular organism you were disinfecting. He had himself within the last few days obtained results which completely astonished him, after nearly twenty years' work on this matter. He failed to kill a sporing organism with a 1 per cent. solution of one of the most powerful disinfectants on the market; whereas he obtained a very considerable effect, though not complete, on those same organisms by the use of one of the permanganates. He was a strong advocate of permanganates, because he believed the nascent oxygen had a selective action that it broke up more easily and attacked more readily the highly complex protoplasm of the bacteria than the comparatively lower organised compounds such as some of those referred to with reference to the decomposition of proteins which were found associated with bacteria. He had found in disinfecting London sewage that it was possible to sterilise it completely by adding permanganate in the proportion of 1 per 1,000, which was not the case with any other disinfectant with which he was acquainted, although there was an enormous amount of organic matter present. The permanganate answered the purpose equally well in the testing under more favourable circumstances as far as they were concerned of pure cultures simply suspended in water. How far this method would help in bridging over the great gap between the academical and practical test of disinfectants he was not able to say, but it seemed to him, knowing nothing but what he had heard, that the difficulties in the way of carrying it out with anything like accuracy would be considerable. First of all in the comparison of the disinfectants one would have to ascertain first whether or no they were electrolytes, and if so what their conductive powers might be. As far as he could see it was hopeless to attempt to compare by that method perchloride of mercury with phenol, one being a true electrolyte and the other not an electrolyte at all. After all, he did not see from what the author had said that he was going to tell them what they wanted to know, namely, how long it would take to sterilise or kill a given organism under given conditions.

Mr. W. C. T. GARDNER said this paper was of undoubted interest, but to his mind it fell short in one point. It did not definitely show the distinct germicidal action of the various disinfectants, but rather dealt with their inhibitory effect, similar to the well-known method which was in vogue at present. He could not understand why, in that method, a bacillus of low resistance, the *B. typhosus*, was chosen as the particular germ for experiment. Would it not have been better to have selected a germ which was more difficult to kill? It was incomprehensible that the agents at present in use, such as formaldehyde or substances containing 50 per cent. of cresols, which were known to be of undoubted germicidal value showed a very low co-efficient. He would like to have these substances worked out by the authors' method and to compare their results with those published by Dr. Rideal.

Mr. O. A. ELIAS drew attention to recent investigations in Germany by Proskauer, Seligmann, and Hans Schneider. These authors affirmed that all absolute results which might be claimed with respect to the disinfecting powers of any preparation were valueless unless distinction were drawn between inhibitory and actual germicidal effect. The main point with these observers was to combat the chief error committed in testing disinfectants, according to the Rideal-Walker method. Dr. Schneider emphasised the necessity of washing out or neutralising any property that might be present likely to hinder the development of growth before finally determining the real value of the antiseptic. This would avoid the confusion that frequently arose between disinfecting action and retardation of development, which in many instances, especially in

the case of a large number of disinfectants containing tar oils, gave rise to the most anomalous results. As regards formaldehyde disinfecting compounds, Seligmann and Schneider pointed out how the retarding action on development might be removed, and observed that a reliable result in regard to the disinfecting action was only obtained by using partially dry test material, and removing the adherent disinfectants by rinsing with dilute ammonia before conveying it into the culture medium. If formaldehyde compounds were compared according to the direct method with carbolic acid, cresol soaps, or such preparations as lysol, there would be better results on the side of formaldehyde. Whereas in reality this was an error, which should be rectified by eliminating its power of retardation; for after 24 to 48 hours cresol soap and carbolic acid, according to the strength of the solution, would show a distinct germicidal action, whilst the formaldehyde under these circumstances only checked the development of the germs, and growth would set in as a rule after the third or fourth day.

The remarks made as to the test of formaldehyde compounds applied in a far greater degree to compounds containing tar oils, and here the authors mention several well-known preparations said to have a very high carbolic co-efficiency, whereas in the case of these substances the true disinfecting test can only be determined by acting on partially dried material carefully rinsed in appropriate fluids, say $\frac{1}{4}$ to $\frac{1}{2}$ per cent. alkaline solutions to wash out the disinfectant before transferring to the culture medium. Whilst a co-efficiency of 15 and more was ascribed to some of the coal-tar products now on the market in England, Seligmann and Schneider point out that these are in reality considerably less powerful than carbolic acid itself.

Mr. JULIAN L. BAKER said it occurred to him when looking at the curves that the difference in the strengths of the organisms might be possibly due to some of varying proteolytic activities being crowded out. The authors took from the original culture sub-cultures at certain intervals and according to the length of time between the first and the last sub-culture so the change of the putrefactive strength altered.

Dr. H. P. STEVENS said he understood the authors did not bring this forward as giving a method for standardising disinfectants, but supposing they developed it in that direction, it appeared to him they would not have to contend with some of the difficulties referred to in reviewing the objections to the Rideal-Walker method, owing to the presence of organic matter; in applying this (the authors') method, there was organic matter in the form of gelatin and peptone.

Mr. J. F. BRIGGS said this method was complicated by the action of an antiseptic on the substratum, and an alkaline antiseptic might have a different rate of effect on the substratum from that of an acid disinfectant quite independently of the bacteria; a mercurial disinfectant would precipitate the substratum altogether and be apparently perfectly efficient. The action of the antiseptic ought to be measured on the bacteria, not on the substratum. That seemed to him a fault of this method.

Mr. C. T. KINCZETT sent the following observations:—

The experiments made by Drs. S. B. Schryver and R. Lessing are very interesting from several points of view and somewhat novel in character, but whether the process be preferable or not to the so-called Rideal-Walker method, it at any rate shares in common with that method its other great limitations and is valueless for determining real disinfecting values. What it does determine is the retarding influence of such antiseptics as may be tested, in so far as they are chemically amenable to the test, in respect of the process of putrefaction as carried on under the particular conditions which are observed. Similarly, the Rideal-Walker method serves to determine the relative germicidal strengths of coal-tar disinfectants under the particular conditions that are observed in conducting the test, but neither process reproduces the conditions under which disinfection has to be carried out in practice and both methods are obviously incapable (and therefore absolutely useless for the purpose) of determining the value of many other preparations, well known to be possessed of great disinfectant properties,

but having different chemical characters to those of coal-tar disinfectants, such, for example, as chlorine preparations, sulphurous anhydride, hydrogen peroxide, formaldehyde, the manganates and the permanganates.

I think there is an objection to the use of faeces for admixture with the gelatin and protein medium, considering that faeces must vary enormously in composition, not only as regards its organic constituents, but with respect also to the organisms with which it is impregnated. This latter consideration doubtless has chiefly to do with the varying incidents of putrefaction of the several mixtures tested by the authors, for in all probability the action of the aerobic organisms has to be either completed, nullified or destroyed before the anaerobic germs can get full play.

Dr. LESSING replied that he could not agree with the argument that this method was a purely academical one. This impression might have been given by the nature of their paper which was more intended to show the scientific principle of the method than discuss its applicability. He thought that it had a stronger claim for practical value than methods working with minute quantities of bacterial growth in an excess of the disinfectant solution, by reason of this ratio being here reversed and imitating more closely the conditions prevailing in the practice of disinfection where there was never any question of acting on the naked germ. Previous methods, such as the Rideal-Walker test, which was an excellent one for the comparative control of preparations of the same type, could only yield a pharmacological factor, and it was agreed on all sides that in the presence even of traces of foreign matter no reliable results could be obtained. With regard to the medium chosen it was, of course, impossible to imitate in any test the conditions of all possible cases; it was too complex a problem to be compressed into one formula or numerical value. They selected the protein medium as a very suitable means of following up the change, but had no doubt that other media, such as those suggested by the Chairman, could be employed under proper precautions. He thought they had given ample proof that the change was due to bacterial action and that it was not brought about by exogenous enzymes. The presence of salt in the medium or the addition of saline disinfectants could only show a different initial conductivity but it would not interfere with the difference in conductivity after putrefaction. For this reason the method was not restricted to coal-tar preparations. These had only been shown in the curves as they had been given considerable prominence of late. The high antiseptic value of formaldehyde, which as Mr. Wynter Blyth pointed out, did not show up in other tests, was very marked by this method. In reply to Dr. Rideal's remarks he pointed out that in most cases where economic efficiency was required, *i.e.*, where preparations are used in great quantity, antiseptics was all that could be desired. There could not be any question of sterilisation in the treatment of drains, floors, stables, public conveniences and places where the bulk of disinfectants went to. On the other hand, where absolute sterilisation was necessary as in surgery, the economic efficiency of the preparation to be used was of minor importance. With regard to the bacteria employed, they had tried pure cultures at first, but found that these did not produce a very rapid change, possibly due to the degeneration of the strains. Under symbiotic conditions the bacteria acted more vigorously and being more resistant allowed a better judgment of the real value of the disinfectant. However, the principle of the method did not imply the use of faeces for infecting purposes and any conditions under which a similar degradation of the medium took place, were acceptable. With regard to the crowding out of the bacteria mentioned by Mr. Baker, this was quite likely, and he thought that whatever the latent period was due to, the method afforded a good means of ascertaining it, and incidentally the age of the culture.

The paper was only of a preliminary nature and the authors would be fully recompensed for their labours if the method would be found useful for the determinations of the antiseptic, if not the germicidal value of disinfectants or preservatives.

Dr. LESSING wrote, in reply to Mr. Kingzett: As I have pointed out in the discussion, our method is not restricted to coal-tar emulsions, but can be applied to such substances as quoted by Mr. Kingzett. As to the use of faeces for infection these have been found to answer the purpose; their employment, however, does not constitute an integral part of the test, but the method can obviously be worked with any other pure or mixed infection which produces degradation in the substrate.

The question of aerobic and anaerobic action has been considered by us and it is quite possible to grow under either condition and then put the cultures to test. This method will thus allow a convenient differentiation between the action of these two types of organisms.

New York Section.

Meeting held at Chemists' Club on October 23, 1908.

THE USE OF PRESERVATIVES IN FOODS.

At this meeting an important discussion took place as to whether chemical preservatives in food are detrimental to health.

Dr. H. W. WILEY, in condemning the use of preservatives in food, dealt with the subject under the following heads:—

(a) Since preservatives have no food value, their addition to articles intended for human consumption is unjustifiable from every point of view.

(b) The addition of preservatives to food substances causes injury to health, though not necessarily immediate injury, as for instance in the case of benzoic acid.

(c) It is illegal, under the Food and Drugs Act, to add preservatives even to specific articles of food which are, by their nature, restricted in consumption.

(d) There is no necessity to add preservatives to food; their use in milk is universally condemned, and ketchup, preserves, pickles, canned meats, and unfermented grape juice, are instances of perishable products which are to be found on the market free from preservatives.

(e) No benefit in the price of food results from using preservatives; inferior materials can certainly be rendered edible by their use, but usually the preserved products possess much lower food value than the pure article.

Mr. READ GORDON pointed out that salting, smoking, pickling, and preserving with sugar or spirit were permitted by law, and yet were considered by many to be quite as injurious, as if not more so, than benzoic or salicylic acids. These acids were found in natural food products, and, when added to foods under proper safeguards, caused no greater retardation of digestive processes than the salt ordinarily taken with food.

Dr. E. E. SMITH dealt with the use of sulphites as preservatives, and criticised the evidence brought forward to show that their use was injurious. He contended, on the other hand, that the evidence went to show that they corrected rather than produced albuminuria; that they did not in any way reduce the number of red corpuscles in the blood; that their oxidation in the body tended to raise the temperature of the blood; and that they had no predominating influence on sulphur metabolism.

Mr. SEBASTIAN MCLELLER argued that, from the commercial point of view, preservatives were unnecessary, and showed that canned or bottled foods, containing no preservatives, were more profitable to the purchaser than the cheap, preserved articles, which were usually made from unsound materials, and were generally of low strength; and gave illustrations of brands of apple butter, baked beans, and tomato ketchup. He also drew attention to the unnecessary and harmful practice of adding alum to pickles.

Mr. HARRIS contended that it was necessary to use preservatives in articles of food in which the bases of ptomaine poisoning were liable to develop.

Mr. L. S. DOW urged the exclusion of preservatives from all pickles, preserves, jellies, tomato products, mince meat, etc.; there was no necessity for their use in a properly conducted cannery using pure fresh materials.

Mr. HARGOOD described the working up of low-grade tomato pulp in preparing ketchup, and pointed out the necessity for using preservatives for this class of product.

Mr. A. W. BITTING described the canning of shrimps without preservatives. The shrimps are kept on ice, washed, boiled in salt water, and canned.

Dr. WILEY replied to the criticisms on his paper.

A letter was read from Dr. E. GUDENAN, arguing that the use of preservatives might be defended on the ground that the system was capable of accommodating itself to poison. He instanced a case in which strychnine had been given in doses increasing from 0.02 grain to 0.1 grain, this latter dose being given for about 500 days; at first the urine gave a strong reaction for strychnine, but later on showed only the faintest traces, even on the full amount voided daily; the patient exhibited no effects of the cumulative action of the poison. In another case, the blood serum of a man who worked continuously in an atmosphere charged with starch dust, had a powerful hydrolysing action on raw starch, and a third case showed that the effect of nitrates was neutralised by accommodation of the system.

MR. S. J. PENTECOST IN THE CHAIR.

THE VOLUMETRIC DETERMINATION OF PHOSPHORIC ACID, MONO-ALKALI, AND DI-ALKALI PHOSPHATES.

BY JOHN M. WILKIE, B.Sc., A.I.C.

The principal methods for the determination of phosphoric acid are the ammonium-magnesium phosphate method and the molybdate method—the former is nearly always gravimetric though volumetric modifications are occasionally employed, the latter lends itself better to volumetric adaptation, Pemberton's process being perhaps the best known. In addition, the uranium volumetric method is also somewhat largely used in technical work, but suffers from many disadvantages, amongst which may be mentioned lack of sharpness in the end point, necessity for standardising on a pure specimen of the substance to be tested, and non-concordant results by the unpractised worker. As I wish to draw special attention to a volumetric method, I shall briefly describe some of the less known volumetric methods.

The lead method involves precipitation as lead phosphate, filtration, and determination of the excess of lead volumetrically in the filtrate. Maly's method involves precipitation as barium phosphate and titration of the liberated acid in presence of phenolphthalein or preferably corallin. The end point is not well marked and the titration must be conducted at boiling temperature. Calcium chloride has also been used (*cf.* Kohn, *Chem. Zeit.*, 1908, 718). Perrot precipitates silver phosphate in the presence of acetic acid and determines the residual silver after filtration by means of a standard sodium chloride solution. (*cf.* this J., 1888, 311.) Holle- mann determined phosphoric acid by conversion to the

disodium salt, precipitation as silver phosphate in the presence of sodium acetate, and determination of residual silver by Vollhard's method (*cf.* this J., 1894, 763, 843).

The main features of any good volumetric process may be enumerated thus:—(a) *Accuracy*—that is consistent and reliable results obtainable only by a reaction which is strictly molecular. (b) *Speed*—The only methods which can lay any special claims to speed are those of Holle- mann and Perrot, and the obsolete method of Maly.

The method I wish to introduce complies with the above requirements. Consider the following equations.

Silver phosphate is readily soluble in mineral acids and also in phosphoric acid, so that on adding silver nitrate to phosphoric acid solutions no precipitation occurs, increasing precipitation taking place as the free acid is neutralised. Silver phosphate is practically insoluble in very dilute acetic acid, as assumed by Holle- mann. It occurred to me that a simple and accurate determination could be effected by precipitating the silver phosphate in presence of excess of sodium acetate and then titrating directly the acetic acid produced in accordance with equation (2) above. Rough experiment seemed to confirm this conjecture so completely that I decided to investigate the matter, and at the same time to extend the method to mono- and bi- basic orthophosphates in accordance with the equations.

Preliminary experiments were carried out with a solution of orthophosphoric acid the strength of which, as deduced from its specific gravity, did not agree well with the figure obtained on titration with $N/10$ barium hydroxide in presence of phenolphthalein.

I might here remark that though direct titration with alkali hydroxide or alkaline earth hydroxide gives good approximations to the actual content of phosphoric acid solutions the point of neutrality indicated by phenolphthalein does not strictly agree with the equation,

The acid referred to above was submitted to careful qualitative examination and found to be free from phosphorous, meta- and pyro-phosphoric acids. The only impurities present were minute amounts of iron and sodium. The real phosphoric acid content was carefully determined both by the ammonium magnesium phosphate method, weighing as magnesium pyrophosphate, the excellent modification of B. Schmitz being followed (*Zeits. anal. Chemie*, 1906, 512), and also by weighing as lead phosphate, proceeding in the usual manner by adding the phosphoric acid to excess of pure lead oxide in presence of nitric acid, evaporating, and igniting to constant weight at low red heat. The results obtained by the first method were 15.17 grms. of phosphoric acid per 100 c.c. (mean of 3 closely concordant results), and by the second method, 15.18 grms. per 100 c.c. The correct strength was taken as 15.17 per cent. w/v.; obviously the lead oxide method returns as phosphoric acid all non-volatile impurities. After various trials the following conditions were found to answer admirably. The equivalent of 0.5 c.c. of the phosphoric acid referred to was transferred to a stoppered cylinder, 26 c.c. of $N/10$ silver nitrate solution was added (no precipitate forms in the absence of chloride), and then 25 c.c. $N/5$ sodium acetate solution; the whole was diluted to about 100 c.c., shaken vigorously, and the acetic acid produced titrated with $N/10$ barium hydroxide solution (*cf.* addendum), adding a few drops of phenolphthalein as indicator. The end point is sharp and easy of recognition. In this connection I prefer the ordinary stoppered cylinders for the titration as the change is particularly distinct, though of course any suitable vessel may be used.

For the 0.5 c.c. of the phosphoric acid solution 23.24 c.c. of barium hydroxide solution were required (the actual figures being 23.23, 23.26, 23.22, 23.25, 23.23 c.c. $N/10$) corresponding to 15.19 grms. of phosphoric acid per 100 c.c.

The close agreement with theory (15.17) is very satisfactory. In the later experiments the precaution was always taken of freeing the acid from carbon dioxide—this was done by boiling in Jena glass vessels for a few minutes, cooling, and then transferring to the cylinder, using the sodium acetate solution for rinsing purposes. In the case of the free acid this precaution is scarcely necessary, but with the alkali phosphates it is absolutely essential. All water used must be freed from carbon dioxide.

Disodium orthophosphate, $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$. The salt used was of a high degree of purity the only impurity present in determinable amount being sulphuric acid; chloride was absent. The crystals were somewhat damp. A solution containing 35.83 grms. per litre was prepared, this solution being decinormal for the hydrogen ion and three times that strength for the phosphoric acid ion. 15 c.c. of this solution was transferred to a small Jena flask, 15 c.c. of $N/10$ sulphuric acid added, and the whole boiled for five minutes to expel carbon dioxide. After rapidly cooling the flask contents were transferred to a stoppered cylinder containing 50 c.c. of $N/10$ silver nitrate solution, the flask being rinsed with 30 c.c. of $N/5$ sodium acetate solution and water; after well shaking the acetic acid produced was titrated as already described, an allowance being made for the sulphuric acid added.

The following results were obtained—given as percentage of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ in the salt: ammonium magnesium phosphate method (Schmitz), 96.84 per cent.; sodium metaphosphate method (evaporation and ignition), 96.98 per cent.; volumetric method, 97.03 and 97.07 per cent. The agreement is again good.

Monosodium orthophosphate, $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$. The salt used was in the form of colourless damp crystals and was free from chloride. As with the disodium salt sulphate was present but in smaller amount.

The results obtained with the mono sodium salt were as follows in percentages of NaH_2PO_4 in the salt, the treatment being exactly as for the disodium salt save that in experiment (2) no sulphuric acid was added. Ammonium magnesium phosphate method (Schmitz), 77.28 per cent.; volumetric method, (1) 78.20 (2) 78.33 per cent. (Theory for the $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$ requires 76.92 per cent.)

The high results obtained by the volumetric method are in all probability due to the presence of free phosphoric acid. This conjecture received confirmation when an attempt was made to determine phosphoric acid as sodium metaphosphate; low results were consistently obtained, no constant weight being obtainable at a bright red heat. In one experiment the first weighing corresponded to 76.92 per cent., and after 30 minutes further ignition this had fallen to 76.28 per cent.

It will be seen that the method as given for mono- and di-sodium phosphates fails in the presence of sodium carbonate. This not unlikely impurity can be readily detected and approximately estimated by slightly modifying the method already given. In the preliminary boiling with sulphuric acid any carbonates present will be converted into sulphates, thus using up some of the acid added, and so low results will be obtained; the full acidity corresponding to the phosphoric acid actually present will not be shown, but the silver consumed in the absence of halogens, etc., will correspond to the actual phosphoric acid content.

Modified method in presence of carbonates. The determination of acetic acid is carried out exactly as already described except that the titration is performed in a 150 c.c. calibrated flask. After noting the alkali consumed, 1 c.c. of normal sulphuric acid is added, the volume is adjusted to 150 c.c. and the contents well mixed. After an hour or so, the flask contents are filtered and the residual silver determined by Volhard's process on 100 c.c. of the filtrate. The results so obtained in all cases have been slightly high, but in the absence of carbonate, the results obtained by the alkali and silver titrations closely agree.

In the modified process alkali chlorides will obviously vitiate the silver, but not the baryta determination; as already mentioned under phosphoric acid, their presence is readily detected in the determination itself when a precipitate of silver chloride will be produced before the sodium acetate is added. This also holds true for the mono-sodium salt, but not for the disodium salt, unless a larger volume of sulphuric acid be added. In any case they can be readily determined by Volhard's method, and a correction applied.

Within limits the exact amount of silver nitrate added is immaterial, but with excessive silver the end point is obscured by precipitated silver hydroxide which does not completely redissolve. The quantities given have been found to work well, and of course the silver solution is not of necessity truly decinormal or even of known value unless carbonates are to be determined.

The author is at present extending the process to calcium phosphates.

The silver nitrate solutions used, when largely diluted, were neutral to phenolphthalein. The sodium acetate was the ordinary trihydrated salt: it was neutral to phenolphthalein.

The author desires to express his indebtedness to Messrs. Boots, Ltd., for the use of their laboratory, in which the work was carried out.

ADDENDUM.

In determining the factor of an approximately decinormal baryta solution the importance of freeing the acid used as standard from carbon dioxide cannot be too strictly insisted on. In the author's opinion this is a point that is often overlooked; his practice is to use $N/10$ sulphuric acid for the purpose, boiling for a few minutes, cooling, and then proceeding as usual; the precipitated barium sulphate does not in any way mask the end point.

Baryta solutions often cause grave inconvenience by crystallizing in the burette owing to changing temperature—an effect specially noticeable in the winter months. This source of trouble and annoyance can be completely eliminated by using a mixed alkaline earth hydroxide solution. A saturated calcium hydroxide solution is prepared and the requisite amount of barium hydroxide, dissolved in a limited amount of boiling water, is then added. After standing a day the solution is decanted and is ready for use.

MR. D. J. PLAYFAIR IN THE CHAIR.

THE VALUE OF THE POLENSKE TEST IN THE ANALYSIS OF OILS AND FATS.

BY R. R. TATLOCK AND R. T. THOMSON.

This method of analysis was introduced by Polenske, whose object was to detect coconut oil, and if present, to determine its proportion, in butter. This was the primary intention, but it has also been attempted to utilise it, in conjunction with other constants, for the detection of animal fat, such as beef fat or lard, in butter. It is with these two points, and with a reference to the application of the method to other oils and fats that we shall deal in this paper. The method of procedure, and the precise form of apparatus employed, were exactly as described in Vol. II., page 853, of Lewkowitsch's book on Oils and Fats. Of course we had in view, and were in agreement with Lewkowitsch's dictum "that it is absolutely necessary to follow the process in all its minutest details, in order to obtain concordant results." There is one detail, however, which has not been generally referred to, and that is the exact amount, and the condition

as regards fineness, of the pumice employed in the process. In Lewkowitsch's volume it is stated that "some powdered pumice" is added, but Harris ("Analyst," Vol. XXXI., page 358) adopts 0.1 gm. as being nearly the amount recommended by Polenske, which was a quantity sufficient to cover the point of a pocket-knife blade. The results Harris gives are only with "three pieces of pumice-stone about 1.5 c.m." and "0.1 gm. of powdered pumice-stone," but still we have no idea of the degree of fineness of the powdered pumice. In the following table are stated results of two butters for insoluble volatile acids which we have obtained with pumice of varying degrees of fineness, and when employed in different quantities:—

Insoluble volatile acids.		
	Butter A.	Butter B.
With two small lumps pumice	2.0	not done
" 0.1 gm. of No. 1 pumice powder	2.3	3.7
" 0.1 gm. of No. 2 pumice powder	2.5	4.1
" 0.5 gm. " " "	2.75	4.4
" 1.0 gm. " " "	2.9	not done.

The No. 1 pumice powder referred to above was ground so as to pass through a sieve with 100 meshes and remain on one with 400 meshes to the square inch, while No. 2 pumice powder was treated in the same way with sieves having 2500 and 3600 meshes, respectively, to the square inch. The soluble volatile acids were practically the same in each experiment, being 29 for butter A and 31 for butter B. In all further tests we have adopted 0.1 gm. of No. 2 pumice powder, as that is quite sufficient to prevent priming, and results can be obtained within 0.1 of each other. In our opinion, however, it is inadvisable to depend upon getting results closer than 0.2 to the truth, as there is a danger of obtaining higher results when the filtration of the alcohol takes longer than usual. Thus an exposure of five minutes may account for 0.1 c.c. of decinormal alkali. Taking everything into consideration, it is apparent that the Polenske method requires delicate handling, and above all it is necessary not to be dogmatic with regard to the bearing of slight differences from the maximum or minimum of insoluble volatile acids found in oils or fats.

Various observers have given the results of their examination of butters by the Polenske method, and have endeavoured to trace a more or less close relationship between the soluble and insoluble volatile acids, but we have not been so fortunate as Polenske himself, for example. That no close relationship existed was plain from the analysis of several hundreds of samples received mainly from sanitary inspectors, but in addition we examined 24 samples, of which 21 were extracted by ourselves from milks from different districts, including the counties of Aberdeen, Dumbarton, Perth, Lanark, and Ayr, while the other three were butters from reliable sources. In order to show the variations in this comparatively small number of butter fats, we may quote the following:—

TABLE I.

showing the variable nature of the relationship between the soluble and insoluble volatile acids in genuine butter fat.

	Soluble volatile acids.	Insoluble volatile acids.
Butter fat No. 1	30.0	2.1
do. No. 2	27.1	2.1
do. No. 3	25.2	2.1
do. No. 4	29.5	2.3
do. No. 5	29.4	4.2
do. No. 6	26.0	1.0
do. No. 7	26.5	2.3

It is scarcely necessary to do more than quote these, the variation being so striking, and especially so as they represent about one-third of the samples tested. It must

also be particularly borne in mind that these are good average specimens of butter fat, as five or six samples of milk (which were undoubtedly mixed milks to begin with) were mixed together for extraction of the fat. The other samples showed very considerable variations, but not so great as those quoted above. The general results are given in

TABLE II.

Number of samples.	Variations in soluble volatile acids.	Average soluble volatile acids.	Variations in insoluble volatile acids.	Average insoluble volatile acids.
6	30 — 32.4	30.9	2.1 — 2.2	2.7
10	28.1 — 30.7	28.8	1.8 — 4.2	2.6
5	26.0 — 27.1	26.6	1.0 — 2.3	1.9
3	24.1 — 25.2	24.9	1.2 — 2.1	1.7

The average for the 24 samples was 28.5 of soluble and 2.4 of insoluble volatile acids.

We shall now deal with the effect of various proportions of cocoanut oil on the Polenske test for butter, the results of our experiments being stated in

TABLE III.

	Soluble volatile acids.	Insoluble volatile acids.
Butter alone	28.1	1.8
Cocoanut oil alone	7.5	18.0
Butter with 5% cocoanut oil ..	27.4	2.4
do. 10% do.	26.2	3.2
do. 20% do.	24.4	4.2
do. 30% do.	22.5	5.7
do. 40% do.	20.9	7.4

The cocoanut oil used in the above trials was extracted in the laboratory from the cocoanut, so that its genuineness is undoubted, and the same oil has been employed in the trials of which the results are recorded later. It is apparent from these results that the possibility of the detection of even 10 per cent. of cocoanut oil in a butter by the Polenske method is very doubtful. One of the genuine butters, extracted from milk in our laboratory, gave 29.4 of soluble and no less than 4.2 of insoluble volatile acids, and, reasoning from analogy, it is most probable that butter fats having about 25 of soluble and 3.5 of insoluble volatile acids may occur in that class of butter. In this connection it ought to be noted that comparatively few butters with low soluble volatile acids have been examined by the Polenske method, so that before giving a final decision on this matter, a much larger number of such butters ought to be analysed. Among the genuine butters we have one showing 25.2 of soluble and 2.1 of insoluble acids, which, on Polenske's original figures, might be regarded as containing at least 10 per cent. of cocoanut oil.

If we now examine the results recorded in Table III., we shall find that the soluble volatile acids in the mixtures are higher, and the insoluble volatile acids lower, than the average of those given by the butter and cocoanut oil separately. Take for example the mixture containing 20 per cent. of cocoanut oil. If we calculate simply on the basis of the butter and cocoanut oil results, we find that the average for soluble and insoluble volatile acids is 24.0 and 5.0 respectively, but the actual results are 24.4 and 4.2, and the same holds good for the other mixtures. It is evident, however, that this is not a true average, as the mixture operated upon was 4 grms. of butter and 1 gm. of cocoanut oil, and it is therefore necessary to know what these quantities will give separately. In making these tests the full quantity (20 grms.) of glycerin was employed, but the amount of caustic soda used was proportionate to the quantity of fat saponified. When the full amount (2 c.c.) of the caustic soda solution required for 5 grms. was employed for 1 gm. of the fat, the mixture

would not clear up, so that the point of complete saponification could not be determined satisfactorily. The following Table (IV.) gives the results obtained:—

TABLE IV.

	Soluble volatile acids.	Insoluble volatile acids.
4 grms. butter fat	22.6	1.7
1 gm. cocoanut oil	4.4	9.1
Mixture of 4 grms. butter with 1 gm. cocoanut oil	24.4	4.2

It will be here observed that there is a deficiency in the soluble volatile acids of 2.6 and in the insoluble of no less than 6.6, and this is most probably due to the retention of the less volatile acids by the non-volatile acids. Another point which calls for remark is with regard to the very high proportion, namely 4.4, of soluble volatile acids obtained from 1 gm. of cocoanut oil as compared with 7.5 from 5 grms. of the same oil. In order to throw some light on this apparent discrepancy, we saponified 1 gm. of butter and 1 gm. of cocoanut oil, respectively, distilled off the usual 110 c.c. which was titrated in the ordinary way, then added 110 c.c. of water to the distilling flask, distilled off 110 c.c. again, and repeated this four times, with the results given in Table V.

TABLE V.

	1 gm. butter.		1 gm. cocoanut oil.	
	Soluble volatile acids.	Insoluble volatile acids.	Soluble volatile acids.	Insoluble volatile acids.
1st distillation ...	6.2	1.0	4.4	9.1
2nd "6	.8	.7	5.6
3rd "2	.6	.2	4.3
4th "1	.6	.15	3.0
5th "05	.5	.10	2.7
6th "05	.5	.05	2.3

If we add together all the soluble volatile acids data 7.2 is obtained, and this is equal to 36 for total soluble volatile acids in 5 grms. As the 5 gm. quantity actually gave 28.1, it is plain that there is practically no discrepancy between the results, when the nature of the method is taken into account. With the 1 gm. of cocoanut oil the figure is 5.6, which is equal to 28 in 5 grms., whereas the actual figure from the latter quantity is only 7.5. This difference cannot be accounted for by the proportion of soluble volatile acids in the residual mixture in the distilling flask when 5 grms. are operated upon, but is manifestly due to the fact that the insoluble volatile acids are only insoluble under the conditions of the process. If these so-called insoluble volatile acids are not quite insoluble, but in reality slightly soluble, then the higher soluble volatile acids in the 1 gm. quantity are accounted for. That this is the case is proved by an experiment made with 5 grms. in the usual way, diluting the 110 c.c. distillate to 550 c.c. with water, shaking thoroughly, filtering and titrating 500 c.c. of the filtrate. Treated in this way the soluble volatile acids were 12 c.c. and the insoluble 1.37 c.c., and although this does not account for the whole difference in the soluble volatile acids, it clearly shows that the so-called insoluble volatile acids are not quite insoluble in water. If the distillate, after dilution, had been heated to boiling and then cooled it is certain that considerably more of the acids would have been dissolved, but it was not necessary to pursue the matter further.

A series of trials was next made with margarine containing various percentages of cocoanut oil, which was the same as was employed in the mixtures with butter, and the following results were obtained:—

TABLE VI.

	Soluble volatile acids.	Insoluble volatile acids.
Margarine alone4	.5
do. with 5% cocoanut oil	1.4	.7
do. do. 10% do.	2.2	1.3
do. do. 20% do.	3.9	2.6
do. do. 30% do.	5.0	3.9
do. do. 40% do.	5.8	5.7
do. do. 50% do.	6.5	7.6

Taking, as before, the margarine containing 20 per cent. of cocoanut oil, it is apparent that the soluble volatile acids are 0.8, and the insoluble volatile acids, 6.9, lower than would be expected from the mixture, thus showing, as in the case of butter, that these acids are retained to the extent stated, by the non-volatile fatty acids. Identical results were obtained with olive oil and beef fat when mixed with the cocoanut oil, after allowing for the slight differences in the composition of the two former oils. This shows that the almost liquid fatty acids of olive oil have quite as great an effect as the more solid fatty acids of beef fat, in retaining the volatile acids.

The question now arises as to the value which is to be attached to the Polenske numbers for the detection and determination of cocoanut oil in butter and in margarine. It must be admitted without qualification that the Polenske test is purely empirical, and it is hedged round by so many conditions that extreme caution must be exercised before coming to a decision as to the presence of cocoanut oil in a butter. It is all very well, as some analysts have done, to show what small proportions can be detected on the condition that one knows the exact composition of the butter which has been mixed with cocoanut oil. But unfortunately for the analyst, he is not in a position to know this, and therefore the Polenske test simply brings him, in some cases, to the doubtful point. This occurs, as far as our experience goes, when there is found a ratio of 9 of insoluble volatile acids to 100 of soluble volatile acids. In such cases resort must be had to the phytosteryl acetate test, and if this proves the presence of a vegetable oil, the probability will then be that it is cocoanut oil, although certainty is out of reach. Where a positive result is obtained, it will probably be safe to regard any excess of insoluble volatile acids as being due to cocoanut oil, and to state always the minimum proportions that may be present. We may add that so far as our trials have gone, we cannot place any reliance on the methods of detecting cocoanut oil which are dependent on silver, copper or baryta values.

As regards the detection and estimation of cocoanut oil in margarine, the Polenske number appears to be quite reliable within limits of say 5 per cent. Basing our calculations on the figures given in Table VI., we have tested margarines of known composition, and obtained results within 3 per cent. of the truth, where there was 35 per cent. of cocoanut oil present. In this connection there is a danger of the analyst reporting a margarine, say on a soluble volatile acids of 6.4, as containing 16 per cent. of butter, if he only determined the soluble volatile acids which seems to be all that he is legally required to do. In a sample of margarine tested by ourselves, the soluble volatile acids were 6.2, and the insoluble 6.6, but this we reported as genuine, as practically the whole of the former was due to cocoanut oil and not to butter. This is a pitfall which analysts must avoid, as they may otherwise wrongly accuse manufacturers of margarine of an infringement of the Sale of Food and Drugs Act, 1899.

As already stated, it has been attempted to utilise the Polenske number as a factor for the determination of animal fat, such as beef fat or lard, in butter. But for this purpose two principles must be established beyond doubt, and these are (1) that a greater proportion of insoluble volatile acids, as compared with the soluble acids, is to be found in butters when the latter acids are high than when they are low, and (2) that the other constants are so affected as to throw them out of their usual relationship to each other. The first of these propositions is founded upon insufficient data, and in our experience facts are

entirely against it, as is shown by the figures already referred to. It may be said that Butter No. 5 in Table I. does not support our contention, but this is an exceptional case, and its composition is probably due to the cow which produced it having been fed partly on cocoanut cake or meal. In fact, the only butters we have found to give such results were from the milk of cows which we had fed in this way, by a farmer, for experimental purposes. It is therefore to be expected that butters having low soluble volatile acids, say about 25, will have a corresponding proportion of the insoluble variety, if the cows received cocoanut meal as a portion of their food. The first proposition therefore remains unproved, or rather is practically disproved, and without it the second proposition is of little account. It is not necessary to enter into an elaborate argument on this point, but we may just put on record the following analysis of a genuine Scotch butter, which, according to the two propositions referred to, would be regarded as containing animal fat:—

Soluble volatile acids	25.2
Insoluble volatile acids	2.1
Saponification value	227.2
Zeiss at 40° C.	43.7
Specific gravity at 100° F.	0.9113
Iodine value	42.71

It is sometimes inconvenient, as occasionally in cheese analysis, to obtain 5 grms. for the determination of the volatile acids, and it is therefore of interest to know the relationship between the results with this and smaller quantities of butter. With this object in view, tests were made with 1, 2.5 and 5 grms., respectively, of two samples of butter, the results being embodied in:—

TABLE VII.

	Soluble volatile acids.	Insoluble volatile acids.
5 grms. No. 1 butter fat	32.4	2.7
2.5 grms. do. do.	16.7	2.4
1 grm. do. do.	7.3	1.8
5 grms. No. 2 butter fat	28.1	1.8
2.5 grms. do. do.	14.7	1.5
1 grm. do. do.	6.2	1.1

These results show that the soluble volatile acids for 5 grms. of butter fat may be obtained approximately by multiplying the result from 2.5 grms. by 1.92, and that from 1 grm. by 4.5. Similarly the insoluble volatile acids for 5 grms. may be approximately obtained by multiplying the result from 2.5 grms. by 1.16, and that from 1 grm. by 1.6.

We have also been making trials with regard to the application of the Polenske test to other oils and fats, so far without finding it of any positive value, but we intend going further into the matter. In the meantime we append the results obtained with several oils and fats:—

TABLE VIII.

Meeting held at Leeds on Monday, December 14th, 1908.

PROF. W. M. GARDNER, M.Sc., IN THE CHAIR.

THE FIFTH REPORT OF THE ROYAL COMMISSION ON SEWAGE DISPOSAL.

BY JOHN T. THOMPSON, M.Sc.

After ten years of deliberation the Commissioners have issued this Report, which deals chiefly with the relative merits of the methods available for the purification of the sewage of towns.

As a result of this delay in publication, the Report is very important as an official confirmation of facts that have been known for some years amongst those working on the sewage problem, but it contains little recent investigation. During the last two or three years, authorities who were compelled to carry out schemes may have spent considerable sums of public money, for example, on storm filters, whilst the Royal Commission held back information showing that these were costly and inefficient. At the same time one must bear in mind the difficulty of the task which the Commissioners have successfully carried out, namely, the collecting of a large mass of evidence and collating with it observations and experiments of their own. They have interpreted their terms of reference wisely and in broad outline the conclusions they have arrived at are excellent, consequently they deserve the gratitude of all engineers and chemists who are responsible for the sewage disposal and general sanitation of our towns. Some of the experiments and methods by which these conclusions were arrived at are open to criticism; the general arrangement of the Report is also somewhat confusing. There is very scanty reference to work done in other countries on this subject.

The following paragraph is noteworthy, and reveals the main principle underlying the whole report:—

"We are satisfied that it is practicable to purify the sewage of towns to any degree required, either by land treatment or by artificial filters, and that there is no essential difference between the two processes, for in each case the purification, so far as it is not mechanical, is chiefly effected by means of micro-organisms. The two main questions, therefore, to be considered in the case of a town proposing to adopt a system of sewage purification are, first, what degree of purification is required in the circumstances of that town and of the river or stream into which its liquid refuse is to be discharged; and, second, how the degree of purification required can, in the particular case, be most economically obtained."

The Commissioners realise that local circumstances vary to such an extent that "the necessary control cannot be provided by direct enactment which could be enforced by the ordinary courts," therefore, statutory provisions in regard to questions of pollution and public health must be of an elastic character. This important principle will be received with general satisfaction.

The Report will be extremely useful in the hands of those who have intimate expert knowledge of all the varied local factors which enter into the question of the sewage treatment of any place, but the danger of misuse by the inexperienced cannot be too strongly emphasised, for it may lead to an increase of the waste of public money which is continually going on, especially in small communities, by the employment of architects and surveyors who have no personal experience of sewage disposal.

PART I.—PRELIMINARY PROCESSES.

Par. 21.—Dr. McGowan's formula for "strength of sewage" seems too empirical, but as Appendix IV. is not yet available one cannot judge how it has been arrived at. It is significant that the Report says that "no statement can be made as to its precise accuracy."

Par. 24.—"Screening" might have been dealt with more fully. It is essential, not only where the sewage has to be pumped, but also where it is necessary to press the sludge.

Par. 29.—With reference to the use of sedimentation tanks in parallel, where the tanks are narrow and adjacent, there is the additional advantage of a short sludge culvert, or better still, the sludge pump may have a suction pipe in each tank, thus avoiding the cost of a culvert and the objectionable manual labour often necessary with tanks in series, where the fall is insufficient.

Par. 50.—The statements about septic tank treatment are in harmony with the usual practice; it is interesting to learn that if septic effluent is treated in settling tanks with "2 to 3 grains of lime per gallon, the suspended solids are reduced from 8 to 5 parts per 100,000, a considerably larger quantity of the liquor can be purified per cubic yard of filter, and the offensive character of the septic tank liquor is largely destroyed." It is a quaint idea to express the amount of precipitant in the time-honoured British unit when suspended solids, etc., are throughout expressed in parts per 100,000.

The advice given about the choice of tank treatment is sound, but considerable knowledge of local conditions are essential to use it successfully.

PART II.—ARTIFICIAL FILTERS.

Pars. 92—98.—Elaborate detailed suggestions are here made as to the volume of liquid which can be treated on contact and percolating beds, taking into account the size of material used in the filters and the amount of suspended solids in the effluent from the preliminary processes. For treating well clarified liquids on contact beds of fine material, 4 to 6 fillings per day are recommended for dry weather, but surely this does not allow sufficient time for proper drainage and aeration of the beds; such statements cannot be based on practical experience with contact beds. When the Report goes on to state, "that the rates of filtration that we give could generally be doubled in wet weather," it reaches the verge of absurdity, for it is almost impossible to fill a contact bed 8 to 12 times per day without serious damage to the bed and the quality of the effluent. Such statements are misleading and tend to encourage the provision of inadequate areas of filters, which would be perpetually overworked. The mass of evidence given before the Commission points to 3 fillings per day in dry weather, increased to 5 or 6 fillings for short periods during storm, as the highest rate at which contact beds can be efficiently worked.

Par. 99.—The remarks on the action of contact beds are important and suggest the need of further investigation. Perhaps more emphasis might have been put upon the value of the period when the bed is standing empty.

Pars. 111—118.—There are eight causes of the loss of capacity of contact beds mentioned, the most important are the disintegration and consolidation of the medium, which can be largely avoided by using durable material graded to an even size; inefficient sub-drainage and overwork; if these causes of decrease are guarded against, the other minor ones will have little effect when a clarified liquid is treated.

The important subject of percolating beds occupies a considerable portion of the Report. Unfortunately the experiments described under this head are open to criticism because of the small size of the beds used and the comparatively short periods over which the observations extended.

Par. 135.—At Horfield a deep bed containing 284 cube yards of medium is compared with a shallow one containing only 27.56 cube yards.

Par. 136.—The Ilford beds had a content of 24 and 12 cube yards respectively, and in both these experiments the distribution was faulty through the use of Stoddart's trays.

Par. 147.—Worse still, at Dorking much time and care was expended on tests carried out with beds with contents of 5 and 10 cube yards. Extreme caution should be used in drawing inferences from experiments carried out on such a small scale.

Par. 149—152.—The experiments with salt solutions are of some academic interest, but do not accurately represent the passage of sewage impurities through a bed.

Par. 153.—These observations lead to the conclusions that, assuming good distribution, a given quantity of coarse material will give about the same result whether arranged as a deep or shallow bed, but in the case of fine materials it is more advantageous to construct a shallow bed.

Par. 159.—The remarks on the most convenient arrangement of percolating beds are of practical utility. An area of percolating beds should be so arranged that portions of it may be put out of work without interfering with the general plant. As side aeration is not necessary for percolating beds, the arrangement of a works would depend chiefly on the configuration of the site and the form of distribution employed; all moving distributors have economic limits, but with fixed forms, such as nozzles, perforated pipes, etc., "there would appear in principle to be no limit to the size."

Par. 161.—It is desirable to be able to form some idea of the relative cost of the various methods of sewage disposal, but the estimates given in the Report do not appear to justify the labour expended on them. They are unfair to contact bed installations for the following reasons:—

(1.) Assuming ample fall, no allowance is made for excavating in the case of the 9 feet percolating beds, but for double contact beds, each 3 feet deep, excavation is charged for the secondary bed.

(2.) To compare fairly in the cost of flooring with the contact beds, the percolating beds should have been 6 feet deep—a much more usual depth than 9 feet, especially where pumping is not employed.

(3.) At large works, anyhow, the cost of labour in a contact bed system would not be double that required for a percolating system.

(4.) £5,700 per acre is an excessive cost for contact beds; the Manchester beds only cost about half that amount. This expensive construction of course tells in favour of percolating beds, for a much smaller area of beds is required in this case.

Par. 168.—The figures for the total constructional cost of the two systems of beds are quite inexplicable, for in some cases this total is less and sometimes several thousands more than the sum of the principal items given.

Par. 177.—Under these circumstances, little value can be attached to the conclusion that on this basis the treatment of tank effluent on "percolating beds costs only about two-thirds as much as purification by double contact beds," although one is convinced that from the standpoint of total annual cost and efficiency the use of percolating beds is the better of the two methods.

Par. 190.—The summary of Part II. shows that where the size of material and depth of bed are arranged to give maximum efficiency, the superiority of percolating beds rests on (1) their ability to treat nearly twice the volume of tank liquor; (2) their ability to readily cope with variations in flow; and (3) the fact that they produce better aerated, and apart from suspended solids, more uniform effluents than contact beds; at Leeds the effluents from percolating beds were generally better nitrated also.

On the other hand, where an offensive tank liquor is being treated, they are liable to produce more smell nuisance, and also more likely to swarm with flies than contact beds. These conclusions have been confirmed at many works.

PART III.—LAND TREATMENT.

This subject has been fully dealt with in previous reports and needs no comment at this juncture, save that the Commissioners very wisely emphasise the fact that sewage farms should be under the best available management, and agricultural results should be quite secondary to the production of a good effluent.

PART IV.—SLUDGE.

The sludge question is, in the majority of towns, the most difficult part of sewage disposal. The Report contains much valuable information, collected from many sources, and one would have liked to have had the subject still further amplified, for it is the chief source of the troubles to which sewage works managers are heir to.

Par. 248.—Little is yet known about the burning or destructive distillation of sludge cake, but the method promises to become a feasible one, if the Mond principle could be applied to sludge cake so as to produce power gas and ammonium salts.

Pars. 253—262.—The experiments on the manurial value of sludge are interesting, but are unsatisfactory, as experiments with manures on one-twentieth of an acre plots and in flower pots for one year always must be. They are of no value to those who are endeavouring to dispose of large quantities of sludge cake to farmers who are willing to pay carriage on it. The fact that the nitrogen and phosphoric acid in cake is in a much less available form than in sulphate of ammonia and superphosphates, should have been the starting point of the experiments and not the conclusion arrived at. It is well known that cake must be put on the land in autumn or early winter to get the best results; it has not time to weather if applied at the same time as quick acting artificial manures in spring.

If the Commission had collected information about the best conditions for applying cake to different crops from districts like Glasgow, where 30,000 to 40,000 tons per year are sent out for agricultural purposes, and where farmers have had experience with this manure for years, the result would have been of great utility to those who wish to dispose of large quantities of sludge cake in this manner.

PART V.—GENERAL.

The treatment of storm water is dealt with in a very satisfactory way. It is a great advantage to have clear official recommendations on a branch of sewage purification which, in the past, has either been entirely neglected or else the provision made for storm water has failed to accomplish much.

Par. 287.—The following paragraph is important:—“In the present state of knowledge, we consider that any regulations in regard to the amount of storm sewage to be treated, and the method of treatment, should be of a tentative character, and that, as regards storm overflows, each place must, to a great extent, be dealt with according to local circumstances. The general principle which should be followed is, we consider, that each local authority should so arrange its sewerage system as to prevent impurified sewage from passing into the river or stream to an extent likely to cause nuisance.”

Again, the Report makes it clear that “the difficulty of dealing with storm water lies, not so much in the actual quantity flowing off an area as the result of rain, as in the rate at which it flows off.”

Storm water is usually most polluted when at its maximum flow, hence the usual overflows on the sewer line, allow the foulest sewage to flow direct into the river during heavy rain.

Par. 295.—The Commissioners consider that the present Local Government Board regulations should be modified, for the special storm filters required therein are found to be costly and inefficient, also the provisions respecting the volumes to be treated are not elastic enough.

Instead of these regulations they recommend as a general rule:—

(1.) Special stand-by tanks of a volume equal to about a quarter of the dry weather flow, kept empty to receive the storm water above about three times the dry weather flow, which should be treated fully in the ordinary tanks and filters worked expansively.

(2.) That any overflow at the works should only be made from these special tanks.

(3.) That no special storm filters should be provided, but that the area of ordinary filters should be enlarged to provide for the filtration of the whole volume requiring such treatment.

(4.) The Rivers Boards or County Councils, as the case may be, shall have power to decide the volume of storm water to be treated, size of stand-by tanks, etc., the Local Authority having a right of appeal to the Central Authority.

If this sound advice is carried into practice it will be a great gain to all concerned. Of course the Com-

missioners recognise that it is impracticable to dispense with the existing forms of storm overflow entirely; for instance, to make the main overflow from the stand-by tanks in cases where the outfall sewer delivers at about river level, would be prohibitively expensive, for it would entail a large spare pumping plant which would only be required on very few days in the year.

Par. 282.—In discussing the choice of a method of sewage treatment, it is made clear that this should depend primarily on local conditions and therefore only guiding considerations are indicated in a general way. The intimate knowledge of these local conditions, which is of such importance to the success of a scheme, can only be attained by prolonged observation and experiment by trained officials: research of this kind cannot be hurried, for some of the most important difficulties in sewage disposal only develop after a method of treatment has been in operation for some years. For example, during the first twelve months a contact bed may give far more brilliant results than a percolating bed, whereas by the end of four years the verdict might be reversed.

The unsuccessful character of many works treating the sewage from small communities, is largely due to the absence of such primary knowledge.

Unless good cheap land, suitably situated, is available, land treatment is not recommended. The results which may be expected from the various processes treating sewages of different strengths are summarised in three tables facing page 202.

This is the first official recognition of the important principle of the expensive use of artificial filters, therefore the rate of filtration given in these tables might have been more clearly defined without compromising the spirit of the Report, which is to avoid fixed legal enactment. For example, this could easily have been done by working out the case of, say, a town with a mean dry weather flow of 1,000,000 gallons per day of average sewage (Class II.), where it is proposed to use continuous flow precipitation tanks and coarse percolating beds 6 feet deep.

From Table II. we gather that “Rate of filtration” per cube per day = 150 gallons, then the maximum rate in storm times = $150 \times 2 = 300$ gallons. Assuming that this town is required to treat three times the mean dry weather flow of storm water completely, then mean dry weather rate of filtration per cube yard per day = $\frac{300}{3} = 100$ gallons, therefore 10,000 cube yards of medium or approximately 1 acre of beds would be required.

Hence it would appear that the term “Rate of filtration” used throughout this Report is merely a figure which may be doubled to get the maximum rate in storm time and only corresponds with the mean dry weather rate in the special case where two volumes of storm water must be treated.

Par. 293.—The Commissioners say, “we think it may be taken that it is practicable to filter three times the mean dry weather flow, and while there are few or no data to show that this is the right amount for which filtration is required, we doubt whether, as a general rule, the filtration of any larger amount will be found to be necessary to prevent nuisance.”

If they had only taken steps to make certain that it will be unnecessary to treat more than three times the mean dry weather flow, it would have avoided much confusion. Then the mean dry weather rate could have been used throughout for expressing the volumes treated on beds, supplemented by the statement that the beds may be used expansively up to a maximum of three times this rate in storm times if it were necessary to treat three dilutions completely. Such a basis would have still been elastic enough to cover the variations in local factors, and would have added a definition to the conception which would have appealed more forcibly to the practical mind, than the basis used in the Report.

Although it is possible that the rates of treatment given in the tables may be attainable when the whole area of beds are at their maximum efficiency, it is doubtful whether such high rates could be maintained in actual practice, especially with a contact bed system. There seems to be little margin allowed for breakdowns or the washing and renewal of material.

Par. 303.—With regard to standards to be applied to sewage effluents, the investigation is still incomplete.

The harm caused by allowing insufficiently purified sewage to flow into streams is summarised under the following heads:—

(1.) De-aeration of the river and consequent injury to fish life.

(2.) Putrefaction of organic matter to such an extent as to cause nuisance.

(3.) Production of sewage fungus and other objectionable growths.

(4.) Accumulation of suspended matter in the river bed or behind weirs.

(5.) Discharge of substances either in solution or suspension which are poisonous to fish or live stock drinking from the stream.

(6.) Discoloration of the river.

(7.) Discharge of intestinal bacteria.

The extent of the purification necessary to avoid the occurrence of all these evil results must vary with the particular circumstances of the town and water course concerned.

Par. 311.—As the Rivers Pollution Prevention Act of 1876 takes no account of this fact, the Commissioners feel strongly that the law should be altered in this sense.

Par. 316.—The recommendations on this subject are of the greatest significance:—

(1.) The Central Authority should determine the tests to be used as standards, and in the first instance prescribes one standard for all non-tidal waters; then the Rivers Boards or County Councils, as the case may be, shall be authorised to raise or lower that standard as local circumstances require, subject to appeal to the Central Authority.

(2.) No action shall be allowed for damages alleged to be due to the discharge of an effluent which complies with the standard fixed for the water into which it discharges, but complaint shall be made to the Central Authority, which shall fix a different standard, if circumstances require it.

Action may be brought in the ordinary courts for alleged damage caused by the discharge of an effluent which does not comply with the standard.

(3.) The Central Authority should have power to suspend the operation of any standard to allow time for construction of works, etc., which justify such suspension.

Par. 320.—A perusal of the replies to questions relating to standards for sewage effluents given in Appendix VII., shows that there is a general consensus of opinion that the mere estimation of the amount of organic matter in an effluent by means of the ordinary water analysis tests is not a reliable index of the effect of the effluent on the stream into which it is discharged; to judge of this a knowledge of the stage of oxidation to which that organic matter has arrived must be obtained. It would be desirable to do this by estimating the total amount of dissolved oxygen that an effluent could absorb during complete oxidation, but unfortunately this process is slow and would occupy two months. Consequently it is necessary to devise some simple, rapid test based on this biological process which is not likely to give conflicting results with different analysts.

Par. 322.—For general guidance the Commission provisionally state that an effluent should not contain more than 3 parts per 100,000 of suspended matter and should absorb less than certain specified weights of dissolved oxygen in 1, 2, and 5 days.

The Commission specify that the suspended matter should be removed before this "aeration" test is applied, but their reason for this is not apparent. To form an opinion of the effect of an effluent on the stream receiving it, the test should certainly be applied to the effluent as a whole. Moreover in its present form this test seems too complex to be useful as a legal standard, and their final pronouncement on this difficult point will be awaited with interest.

The attention of chemists should be drawn to the account of Dr. Adeney's interesting and laborious research on the "Course and Nature of the Fermentative Changes in Natural and Polluted Waters, as indicated

by the Composition of the Dissolved Gases," published in Appendix VII. Amongst other important results it is demonstrated that the fermentation of substances under aerobic conditions by the organisms usually present in water, takes place progressively in two distinct stages, (1) that in which the organic substances are completely broken down, the carbon and nitrogen being largely converted into carbon dioxide and ammonia, a little organic matter remaining as such, but in an altered form; (2) that in which ammonia is oxidised to nitrous or nitric acid or both; during this stage some of the organic matter remaining from (1) may be further oxidised to carbon dioxide and possibly also to nitric acid.

This research is an important step towards ascertaining the nature of the complex changes which take place during the aerobic purification of sewage. As a result of his experience, Dr. Adeney (Appendix VII., page 5) suggests a series of standard tests based on the ratio of dissolved oxygen to dissolved atmospheric nitrogen remaining in aerated mixtures of tap water and effluent, after standing 24 hours at 60° F. These standards are perhaps too elaborate for practical purposes, yet every-thing points to the adoption of some modification of the "aeration" test, together with a limit to the amount of suspended solids, as the ultimate standards for sewage effluents.

Par. 356.—The whole of the recommendations of the Royal Commission centre around the creation of a new Central Administrative Authority, with the local Rivers Board as a first tribunal.

Much difference of opinion has been expressed on this point, but in theory, at least, the proposal should give general satisfaction; for it seems eminently desirable that the vital questions indicated should be dealt with in a comprehensive manner. For instance, it is very essential that the water supplies of this country should be protected, and utilised to the best advantage for the benefit of our dense population.

Our past experience of Government Departments is not encouraging, yet if this new Authority were so constituted that it would break away from old traditions, and carry out its work on broad, progressive lines so as to lead, not hinder, those who are working out the many details of the vital problem of sanitation, it would be a great boon to our national life.

DISCUSSION.

Prof. W. M. GARDNER said that he gathered that on the whole the Report was a very satisfactory one. It appeared probable that improvements were not likely in the future to bear so much on fundamental points as on details.

Dr. G. J. FOWLER appreciated Mr. Thompson's difficulty in summarising the Report, as he himself had made several attempts to do the same. He was pleased Mr. Thompson did not depreciate contact beds. The confusing figures given in the Report with regard to them could probably be explained by making an allowance in the later fillings for water held up in the pores of the beds, this causing decreased capacity. He agreed that these beds could not be used for more than six fillings per day. On the whole he agreed to the recommendations of the Report, though not to the grounds for them. With regard to costs, the endeavour to give definite estimates had resulted in a series of figures of little practical value. These tables should be taken simply as indications of the lines on which estimates should be made, since there was great variation in different places. The estimates given might unfortunately be used to support individual ideas. He thought more general principles should have been embodied in the Report, since the limits of success in several directions were now known. For instance, in dealing with sludge, the difficulty was not in getting it out of the sewage. Much depended on its nature. Sludge from percolating filters was dried more easily than chemically treated sludge, because grease was removed by oxidation in the biological processes. Sludge from percolating filters had not been tried in the agricultural experiments quoted. Sludge cake from chemical treatment disintegrated very slowly. It might pay to wash filter beds, since chemical

treatment increased in cost far more than the efficiency of the resulting purification. He thought a properly regulated Central Authority might do much good, not only in consolidating and guiding the work of individuals, but also in controlling the sources of water supply, and preventing their monopoly by a few large towns.

Dr. H. MACLEAN WILSON advised those who meant to read the Report to cut out about two-thirds of it which dealt with detailed matter on first reading, so as to avoid confusion resulting from mixing this up with the main body of the Report. There were important omissions on the subjects of screening, comparative results of treatment of the same sewage by different methods, and the nature and amount of chemicals to be used in precipitation. The suggestions for standardising sewage were, on the one hand, impracticable, and on the other hand, too empirical and artificial. The formula proposed was evidently not a good one if it had to be varied for different sewages. The question of suspended matter from percolating filters had only been indirectly mentioned. The removal of this matter should not be neglected, since it contained a considerable proportion of polluting matter. It often accounted for as much as fifty per cent. of the oxygen absorbed figure. The question of storm water was not treated in the best way. He was sure the stand-by tanks suggested were better than storm filters, but what was to become of their contents after the storms? With regard to fine and coarse material for percolating filters, he feared filters of fine material were certain to become blocked. He agreed with Dr. Fowler about washing the percolating filters, but did not see how this would work with fine material. He thought the old standard required, viz., that every sanitary authority and manufacturer should use the best available means for purification of sewage and refuse, was the most satisfactory. Any arbitrary fixed standard would put those who had to fix it in a very awkward position, and any variable standards for different localities would leave them still more at a loss as to what to advise.

Mr. G. A. HART thought the Report might be a very dangerous weapon if used indiscriminately in the hands of those without technical knowledge of sewage purification. The Local Government Board had hitherto adjudicated upon such schemes and such an authority must be largely influenced by general considerations and questions of precedent. He regarded the Report as laying down the basis for guidance in prospective legislation. The general recommendations of the Report were good, especially so the expansive volumetric basis for those works constructed for the filtration for storm water, and the consolidation of views with regard to percolation filters. So far no such recognition had been given to those works and only the experience of a few particular places had supported them.

Mr. W. McD. MACKEY was interested to hear lime was now used without slaking, and asked if it would not be more under control if in the ground condition.

Mr. T. FAIRLEY was pleased to hear that the general opinion was that the recommendations were good, but thought it a defect that so little reference to the experience of other countries was supplied.

Dr. H. T. CALVERT would have liked to hear the general opinion on the proposed standards. The suggested formula seemed very empirical and he hoped the Appendix still to be published would justify its use. It seemed a pity that England, which had done so much to solve the fundamental problems of sewage purification, should now be so backward in filling in the details, thus leaving other countries to get ahead of us in this respect.

THE TANNAGE OF SOLE LEATHER WITH MIMOSA BARK.

BY H. G. BENNETT.

(See this J., Dec. 31, 1908, pp. 1193-1195.)

DISCUSSION.

Mr. W. B. HILL said he had tried experiments with mimosa bark without the use of salts but obtained a

product which was too soft. It would be interesting to know what percentage weight of leather was obtained by this process.

Mr. A. G. PERKIN asked what views Mr. Bennett held as to the chemical nature of the astringent tannins. Catechol was probably a constituent of mimosa bark tannin and could condense to form phlobaphenes. It seemed to him that in the extraction of the bark with water the pure tannins were first obtained in solution and the part which was extracted with difficulty consisted of the phlobaphenes which had been formed in the plant itself.

A MEMBER inquired whether it was not now recognised that the tannins from galls were not glucosides as was formerly supposed?

Mr. H. G. BENNETT, in reply, said that although mimosa bark gave leathers which remained soft to the end of the tanning, the drying caused the product to become wonderfully firm. Mimosa bark tannin had now been known for some time, and was a staple tanning material in Australia and the Cape. The acacia had been successfully transplanted to Natal, and was now exported to Great Britain, and was of increasing importance to British tanners. Most of the astringent tannins were catechol tannins, but some catechol tannins, e.g., gambier, were very mellow. Astringency was, however, probably connected with the chemical constitution. Mimosa bark gave "reds" or phlobaphenes but the leather obtained was not so dark as that from quebracho. A good deal of doubt existed even yet as to the constitution of gall-nut tannin. He thought catechol tannins were not glucosides because the amount of sugar naturally associated with mimosa bark was very small and these tannins possessed no souring properties. On the whole the best results were obtained by using a combination of catechol and pyrogallol tannins.

Obituary.

THOMAS WARDLE.

SIR THOMAS WARDLE, one of the greatest authorities of the day on sericulture and all branches of silk manufacture, was born at Leek, in Staffordshire, on January 26th, 1831. He was educated at the local grammar school and at Macclesfield, and entered commercial life at an early age. Having taken up business as a silk-dyer and finisher, he extended his operations to silk and calico-printing. Thomas Wardle was the first to discover a satisfactory process for dyeing the wild tussur silk of India. At the request of the King (then Prince of Wales) specimens of the early results of his efforts in this direction were placed in the Indian Section of the Paris Exhibition of 1878. They were afterwards removed to the South Kensington Museum. They included the first piece of plush made from tussur silk, from which was originated the now considerable Yorkshire industry of "seal cloth," an imitation of sealskin, chiefly prepared from the waste of tussur silk. For several years a "Wardle Collection" of bleached and dyed Indian silks was on exhibition at Lyons; there Thomas Wardle came into close association with the leaders of the silk industry in France. He acted as a juror at the International Paris Exhibition of 1878-9, and was made a Chevalier of the Legion of Honour. He was an original member of the Society of Chemical Industry, and a member of Council (1905-1908). He was also a President of the Society of Dyers and Colourists. At the instance of Sir George Birdwood, who had been the first to call attention to the great possibilities of the commercial utilization of Indian tussur, the Secretary of State for India sent Thomas Wardle out in 1885 to report on sericulture in Bengal, and to collect typical silks from various parts of the country for the then approaching

Colonial and Indian Exhibition at Earl's Court. Several other visits to India subsequently followed, succeeded by reports and advice, which did much to improve methods and to advance the growth of this branch of Indian trade. His most conspicuous service there was the revival of the industry in the Valley of Kashmir. Innumerable difficulties were overcome and a moribund industry was placed upon a footing of prosperity. The whole story is told by Sir Thos. Wardle in his "Kashmir and Its New Silk Industry" (1904). At the Royal Jubilee

Exhibition, Manchester, 1887, he was made Chairman of the Silk Section, when he brought together a magnificent collection, and drew up an exceptionally fine illustrated handbook for his Section. He received the distinction of knighthood in 1897, and was made honorary expert on silk of the Imperial Institute. Sir Thomas Wardle was President of the Silk Association of Great Britain and Ireland, and Hon. Secretary of the Ladies' National Silk Association. He died on Sunday, Jan. 3, 1909, at his residence, Leek, Staffordshire.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Dissolving gases in liquids; Apparatus for—W. Hommel and The Metals Extraction Corporation Ltd., London. Eng. Pat. 27,019, Dec. 6, 1907.

THE invention is particularly applicable to the solution of sulphurous acid in water and to the delivery of predetermined quantities of the solution. The solution vessel, B, is connected with a water supply tank, A, fixed

at a definite height above it, by the pipes, D, E. It is also provided with a gas supply pipe, C, and a solution delivery pipe, F. The three pipes, D, E, F, have valves, D², E², F², all of which are connected to the lever, G, so that they can be operated simultaneously, the valves, D², E², being open when F² is closed and *vice versa*. The apparatus is operated in the following manner. The valves, D², E², being opened, and F² closed, a quantity of water flows from the tank, A, into the vessel, B, until it is filled to the level of the lower end, E¹, of the pipe, E. Sulphurous acid or any other desired gas is then pumped under pressure through the pipe, C, and dissolves in the water, any excess escaping through the pipe, E, which is momentarily unsealed. The valves are then reversed and the solution is forced out by the pressure of the gas through the pipe, F, until the level falls below the end, F¹, of the pipe, F. The quantity of liquid delivered at each operation is regulated by adjusting the depth to which the pipe, F, dips into the liquid in B. If desired, some gas may be passed into the tank, A, through the pipe, H, in order to partially saturate the water and shorten the time necessary to obtain the solution in the vessel, B.—W. H. C.

Centrifugal drying machine. R. Williamson, Motherwell. Eng. Pat. 28,356, Dec. 24, 1907.

THE elastic buffer which supports the spindle of the machine or its collar, is constructed of two or more rings of rubber or other suitable elastic material, separated by loose distance pieces. The object is to obtain a better control of the gyratory motion of the spindle.—W. H. C.

Centrifugal apparatus for separating solids from liquids. Aktiebolaget Separator. Fr. Pat. 392,702, July 25, 1908. Under Int. Conv., July 27, 1907.

THE patent relates to improvements in apparatus of the type described in previous patents (see this J., 1904, 895; 1905, 1162; 1906, 9). One or more of the vanes are allowed to project outside the outer plates of the centrifugal separator disc, in order to protect the other vanes from injury, and to minimise wear and tear on the latter. Protecting pieces may be suitably attached to these projecting vanes in order to facilitate renewal when worn.—C. J. G.

Centrifugal dryer. F. J. H. Bromham. Fr. Pat. 393,415, Aug. 17, 1908.

THE claim is for a centrifugal machine having a horizontal axis, from which the dried material can be intermittently or continuously withdrawn by a pipe, the end of which is provided with scrapers and which is moved vertically

and also horizontally parallel to the axis of the machine. The material to be dried is delivered by a worm-wheel on to an adjustable inclined plate which directs it on to the perforated periphery of the centrifugal drum.—W. H. C.

Dry products from liquids and semi-liquids; Obtaining —, D. M. A. G. Hawes, London. Eng. Pat. 4549, Feb. 28, 1908.

THE claim is for improvements in the apparatus described in Eng. Pat. 1479 of 1906 (this J., 1907, 110), and in application for Eng. Pat. 17,323 of 1907. Two or more perforated rotating chambers are arranged within one outer casing, or the chambers may be constructed of sheet metal, not perforated, and have only their upper ends enclosed in a casing, into which the current of hot air for drying is delivered. The powder resulting from the operation is removed from the bottom of the chambers by a screw-conveyor and from the air scrubbers by brushes or flexible flaps, which are kept in flexible contact with the walls by the centrifugal force resulting from the rotation of the chambers. The rotary chambers may also be constructed of a pear-shape with the apex uppermost.—W. H. C.

Dryer. J. W. Biles, Louisville, Ky. U.S. Pat. 907,219, Dec. 22, 1908.

A ROTARY drying drum has a "heat-conduit" arranged concentrically within and adapted to be rotated. The "heat-conduit" is provided with projections or shelves upon its periphery. The angles at which the shelves project, can be adjusted, and the material which is fed into one end of the drum is lifted by projections from the latter and dropped on to the projections on the conduit, from which after a short interval it again falls back on to the bottom of the drum. It is in this way alternately lifted and dropped, being at the same time moved forward towards the other end of the drum, from which it is discharged.—W. H. C.

Dryer [for paper, etc.]. M. E. Dejonge. Fr. Pat. 393,199, Aug. 11, 1908.

THE claim is for the construction of the casing of the drying chamber of incombustible and heat insulating materials. The casing has an iron frame covered by shutters formed of sheets of asbestos held between metallic gauze or perforated metal sheets.—W. H. C.

Drying apparatus. A. von Dehn. Fr. Pat. 393,273, Aug. 13, 1908.

THE apparatus consists of a horizontal jacketed drum provided with a longitudinal shaft, passing through stuffing-boxes at either end and rotated by suitable gearing. The shaft carries a coil, to the extremities of each whorl of which, agitator plates are fixed. Steam is passed through hollow journals into the coil, and heated air or gas is passed through both the drum and the jacket, which latter has partitions to force the gas to take a tortuous path. When the greater part of the liquid has been evaporated, the current of gas passing through the drum itself is stopped, and a vacuum is created within the drum to complete the desiccation, the passage of gas through the jacket and of steam through the coil being continued.—W. H. C.

Filter-press frames. E. Feix, Tüppelsgrün, Bohemia. Eng. Pat. 5944, March 17, 1908.

THE claim is for a method of securing the rubber packing by which the joints between the metallic (tin for beer filtration) plates or frames of the press are made tight. The packing, which has a dovetail section, is inserted into a rectangular groove formed near the edge of the plate. The outer wall of the groove is then pressed inwards by a roller, so that the rubber packing is gripped tightly.—W. H. C.

Earthenware cocks and pipes. M. Henss, Nied on the Maine, Germany. Eng. Pat. 15,189, July 17, 1908. Under Int. Conv., Jan. 11, 1908.

A LAYER of wire-netting is placed over or around the earthenware pipe or cock and a protecting casing of lead or other suitable metal is cast around the netting so as to surround the cock or pipe. The wire-netting serves to strengthen the metal casing.—W. H. C.

Temperature fluctuations; Apparatus for indicating —, J. E. Hedin, Lidköping, Sweden. Eng. Pat. 15,273, July 18, 1908.

TWO spiral wires, tubes, or bands which alter their shape when heated or cooled, are rigidly fixed at their inner ends to adjustable pins, by which the instrument can be set, and have their outer ends free. They are formed of dissimilar metals having different coefficients of expansion. One spiral is enclosed in a heat-insulating cover and the other is freely exposed to the influence of the temperature it is desired to indicate. Each spiral is connected by a conducting wire to an electrical indicating device, such as a bell, and carries a contact piece at its outer, free end. On expansion of the coils taking place, the contacts touch, the circuit is closed, and the bell or other device indicates that the predetermined temperature, for which the instrument was set, has been reached.—W. H. C.

Kiln. W. Ward, Mitchell, Ind. U.S. Pat. 906,174, Dec. 8, 1908.

THE air-supply for the kiln is preheated by aspirating it, by means of an injector, through a series of arched flues over the grate.—W. H. C.

Calclner. C. De Jonge and W. Nevers, Grand Rapids, Mich. U.S. Pat. 907,575, Dec. 22, 1908.

TWO vertical concentric tubes are connected at their ends by annular heads. The diameter of the inner tube is reduced in its lower part; this tube is provided with an interior ledge at a distance from its ends; on this ledge is supported a diaphragm. In the upper part of the inner tube is placed an agitator. Flues extend into the lower part of the inner tube, and pass through the upper annular head to an annular breeching. The inner tube is provided with a cover, through which pass an outlet pipe and a pipe communicating with a blower.—A. G. L.

Fume-condensing apparatus. L. C. Laurent, Denver, Colo. U.S. Pat. 907,379, Dec. 22, 1908.

THE furnace is connected to the chimney or stack by a flue which slopes downwards from the stack to the furnace. Liquid is sprayed into the flue by a number of jets, the orifices of which are turned towards the stack so that the draught may not be impeded. A gutter formed on the bottom of the flue collects the liquid and guides it into a number of outlet pipes passing through the bottom of the flue.—W. H. C.

Emulsions; Preparation of —, W. G. Schroeder. Ger. Pats. 204,061 and 204,062, July 26, 1907.

(1). THE process consists in preparing the emulsion in a series of mixing vessels connected only by narrow tubes. The mixing vessels are jacketed, and each is provided with an agitator, the rate of rotation of these agitators decreasing

regularly from the first vessel to the last of the series. The mixing vessels are arranged step-wise one above the other, the components of the emulsion being introduced continuously into the top vessel, and the emulsion drawn off from the bottom one. (2). An apparatus for the preparation of emulsions is shown in the figure. A rapidly rotating shaft, *E*, carries the block, *b*, which has an annular grinding surface, *c*, bearing against a fixed annular grinding surface, *n*. In the space between the two grinding surfaces is a turbine, *f*, which is fixed to *n*. The liquid to be emulsified enters at *g*, and is forced under high pressure, between the two surfaces, *b* and *c*, the emulsion being then withdrawn from the arrangement.—A. S.

Distilling, evaporating, heating, or cooling liquids. O. Brücke, Fr. Pat. 392,986, Aug. 6, 1908.

The apparatus consists of two concentric tubes, *b*, *e*; the liquid to be treated enters by the pipe, *a*, flows upwards through the inner tube, *b*, overflows through the holes, *d*, into the annular space, *m*, and trickles down the outer surface of the tube, *b*, in a thin film, finally escaping through *f*. The gaseous treating medium enters partly through *g*, flowing in the same direction as the liquid through *b*, and partly through *h*, flowing in the opposite direction to that of the liquid through *m*. The gaseous medium along with any vapour given off passes from *m*, through the perforations, *k*, and escapes along with that from the inner tube, *b*, through the pipe, *i*. If desired a heating or cooling jacket may be interposed between the two tubes and the gas given off in each may be collected separately.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

Peat for industrial and metallurgical purposes. E. Nystrom, J. Canadian Min. Inst., 1907, 11, 231—235.

AIR-DRIED machine-made peat is said to have a fuel efficiency equal to 55 per cent. of that of ordinary coal, but the cost of handling and transporting so bulky a material, and the readiness with which it absorbs moisture, greatly decreases its value. Suction producer gas may be produced from peat containing up to 45 per cent. of moisture, though it is recommended that for this purpose the moisture should not exceed 30 per cent. Some retort-made peat coke manufactured in Germany and Russia (see this J., 1907, 1270) is said to compare favourably with charcoal for blast-furnace and other metallurgical purposes. Three tons of air-dried peat are required to produce one ton of coke, and the non-condensable gases are utilised for heating the retorts. A new method of manufacturing peat fuel consists in reducing the peat to a pulp, and without drying, subjecting it, under a pressure of 5—10 atmospheres, to a temperature of 150—175 °C. The carbonised material is then filter-pressed, dried, and briquetted. The fuel has a calorific value approaching that of ordinary coal and does not absorb moisture.—F. R.

Coke-oven gas; Utilisation of —. E. Cuvelette, Soc. Ing. Civ. de France, Proc.-verb., 1908, 243—245.

THE successful application of blast-furnace gases in gas-engines points to a similar utilisation of coke-oven gas.

In modern regenerative by-product ovens about 40—50 per cent. of the gas generated is available. It must be passed through purifiers to remove tar, sulphur, and cyanogen compounds before it can be used in engines. Thus purified, it is very rich in hydrogen (50—60 per cent.). Up to the present, engines using this gas have been installed on the Continent to a total of about 40,000 H.P., mostly of the double tandem type; the largest yield 1200—1500 H.P. Careful trials in the Cockerill works have shown that 1 kilowatt at the terminals is yielded by a consumption of 1 cb.m. of gas of 4000 calories per cb.m., whilst 2½ cb.m. of the same gas are required to generate the same energy by means of boilers and turbines.—J. T. D.

Water-gas production in vertical retorts; Economy of —. B. Strache, J. Gasbeleucht., 1909, 52, 12; E. Körting and Geipert, *ibid.*, 13.

(1). STRACHE criticises the conclusion of Körting and Geipert that it is economical to introduce steam into vertical retorts towards the end of gasification (see this J., 1908, 1143). From the results obtained in water-gas producers, it is argued that if 80 per cent. of the steam is decomposed, the yield of water-gas in a vertical retort would not exceed 5.1 cb.m.; the actual yield of 36.5 cb.m. is only realised by passing steam through the retort for 1½ hours, and probably 90 or 95 per cent. of the steam is not decomposed. (2). Körting and Geipert state that actual measurements show that in the vertical retorts, 0.568 kilo. of steam is used per cb.m. of water-gas formed, as against 1 kilo. in a water-gas plant. It is pointed out that Strache takes no account of the greater depth of the bed of hot coke in a vertical retort, nor of the external heating of the retorts during the introduction of steam.—A. T. L.

Thorium. C. Baskerville. See X.

Water gas, suction gas, and other gases in factories; Memorandum as to the use of —. Factory Department, Home Office, Dec., 1908. Form 827. [T.R.]

Carbonic oxide poisoning.—In recent years there has been great extension of the manufacture and use of water gas and other gases of a similar nature (suction gas*, Dowson gas, Mond gas, power gas, producer gas, blast furnace gas, &c.) for driving gas engines, heating furnaces and boilers in factories, welding, soldering, and many other industrial purposes. The particular danger associated with all these gases is that of poisoning by carbon monoxide, which is also a constituent of ordinary coal gas; but whereas the proportion in coal gas varies from 4 to 12 per cent., in carburetted water gas it reaches 30 per cent., and in uncarburetted water gas 50 per cent. The other gases named above usually contain from 10 to 25 per cent.

The use of these gases was the subject of an inquiry in 1899 by a Departmental Committee, who recommended in their Report† that the manufacture and distribution for heating and lighting purposes of any poisonous gas which does not contain a distinct and pungent smell should be prohibited, and that regulations should be made limiting the proportion of carbonic oxide. In recent Acts authorising companies and local authorities to manufacture and supply Mond or similar gas for motive or heating purposes it is required (1) that the gas shall be strongly scented; and (2) either that the proportion of carbonic oxide in the gas shall be limited to 11 per cent., or the Secretary of State may impose regulations to protect against the risk of poisoning. It is made the duty of the Inspectors of Factories to enforce these provisions as regards factories and workshops in which the gas is used.

The Annual Reports of the Factory Department during the last eight years show a steadily increasing number of

* The name is derived from the fact that every suction stroke of the gas engine draws the vapour (previously heated) into the generator, with which the engine communicates directly without interposition of a gasholder.

† Report of Water Gas Committee, 1899, on the Manufacture and Use of Gases containing a large proportion of Carbonic Oxide. C. 9164. Wyman & Sons, Ltd., Fetter Lane, E.C. Price, 1s. 2d. by post 1s. 6d.

reported cases of poisoning by carbonic oxide on manufacturing premises. Thus in the five years 1899 to 1903 there are references to 51 cases (17 fatal), in the two years 1904 and 1905 to 57 (18 fatal), and in the two years 1906 and 1907 to 136 (14 fatal). The lessened mortality is due possibly to better knowledge of the methods of resuscitation. This list does not include the slight cases of partial unconsciousness of which there is mention, entailing only a few hours' absence from work. These casualties were traced to several causes, among which may be mentioned:—(1) leakage from joints or taps in engines, or in pipes and flues conveying gas; (2) gradual escape of gas into a small engine-room, weigh-cabin, office, or the syphon-pit of the Dowson apparatus; (3) cleaning and repairing of engines and of tanks, scrubbers, or blast furnace flues, before a sufficient time had been allowed for the gas to escape; (4) inefficient disconnection from the blast furnace of the flue during cleaning; (5) charging cupola furnaces at raised platforms; (6) percolation of gas, through several yards of soil, from underground flues; (7) conveyance by the wind of gas escaping from defective reservoirs, or of waste gas allowed to blow off unburnt, through ventilators and open windows into workrooms at some distance from the generating plant; (8) incomplete combustion of gas in defective gas ironing machines; (9) ignorance of danger and of the earliest symptoms produced; (10) inodorous nature of the gas; (11) working alone; (12) lack of rescue appliances.

More particularly in connection with suction gas plants the constantly recurring cases of poisoning are evidence of the care necessary in installation and working. Accidents have happened by reason of faulty situation in cellars, or in places inadequately ventilated. They emphasise the desirability of posting up in the engine-house a cautionary notice (such as is now issued by some manufacturers of gas engines) with the necessary routine instructions, *e.g.*—

(1.) *Starting*.—The main stop valve must be shut and the chimney valve opened; otherwise gas will escape into the room, owing to the pressure set up by the starting fan.

(2.) *Stopping*.—As soon as the stop valve of the engine is shut, the chimney valve must at once be opened, so as to allow the gas to escape into the open air.

(3.) *Charging with coal*.—The head must never be placed immediately above the hopper.

(4.) *Testing*.—All air must be drawn out of the washers and pipe before any light is applied so as to avoid an explosion, and the cock must always be closed between tests.

(5.) *Cleaning and repairing*.—After the fire is quite out, air must be blown through by the fan, and the generator doors opened; and the plant must then be left for several hours *before any cleaning is done*. Cleaning should be done by daylight; and no fire, naked light, or smoking must be allowed near the plant.

Other special precautions may need to be mentioned in the notice; thus where one of a range of boilers fired by waste blast furnace gas has to be disconnected for internal sealing and flue cleaning, disconnection should be complete, either by a running joint or a short piece of pipe which can be removed—preferably a flange pipe; and while anyone is inside the boiler, a man should keep watch outside.

Carbonic oxide poisoning may occur in other ways apart from the manufacture or use of the particular gases named. Thus danger of this kind may arise in laundries from the use of gas irons, and in workrooms from defective gas fittings (especially absence of stop-pins indicating the cutting off of gas) and from gas stoves not provided with chimneys or flues for carrying off the products of combustion. The absence of a chimney in a room greatly increases the risk. Carbonic oxide is found also in lime kilns, cement works, and where braziers and coke fires are used in confined spaces.

Preventive measures.—The precautionary measures to be considered must vary somewhat according to the manner in which the gas is manufactured and used in different works, but the following are of general application:—

(1.) The structural conditions should be such as not to entail unnecessary risk; thus—

(a) The suction or other gas engine should not be in a confined space or in a basement or sunk room, but in a room or shed properly lighted and adequately ventilated (by special openings and by a fan where practicable) to the outer air, and either without doors or with doors cut away at the top or bottom.

(b) The air intake for the engine should be from the open air, and not from the engine house itself. The same observation applies to the silencer or air-box, if any.

(c) The vent pipe through which the gas main to the engine is cleared of air, or any similar vent pipe, should never end inside a building, but always outside, and at least six feet from the ground.

(d) The openings giving access to any part of the gas circuit should be few, and in positions as safe as possible, and opened only in cases of real need, and by responsible persons.

(2.) A competent person should be made responsible for inspecting at stated short intervals all valves and connections, to see that there is no leakage; and for keeping a signed and dated record of such inspection.

(3.) A notice, mounted on a board, should be affixed in the engine room or gas-plant house, as recommended above.

(4.) No person should be allowed single-handed to execute work in a place where exposure to the poisonous gas is to be anticipated.

(5.) No workman should enter, or approach when opened, the holder or other part of the gas circuit until the gas has been well flushed out by fresh air.

(6.) A cylinder of compressed oxygen, fitted with lever key, nipple and union, and rubber gas-tubing with mouthpiece, should be kept in constant readiness. The apparatus should be in charge of not less than two persons* instructed in its use. At least once a month it should be examined by them, when the condition of the mouthpiece and of the rubber tubing should be observed. If the rubber becomes hard and dry, warm water will restore the pliability.

(7.) Ropes should be provided for rescue purposes, and the place where they are to be found stated on the notice (par. 8). Where dangerous work is foreseen, special rescue appliances should be supplied, such as those now kept in many chemical works and coal mines; they supply the rescuer with air or a mixture of oxygen and air, so that he does not breathe the poisonous gas.

(8.) Further notices should be affixed in the works, explaining the deadly nature of the gas, the symptoms of poisoning, and the means of rescue and "first aid."

(9.) The workmen should be practised in rescue drill, including the use of the appliances provided. They should be further instructed by a medical man in artificial breathing and administration of oxygen. They should be especially warned of the danger of exposing a "gassed" person to cold.

(10.) Men in charge of any engine worked by poisonous gas, or of any apparatus in which such gas is stored, or otherwise exposed to risk of inhaling it, should be free from any disease of the heart and lungs. Employers would do well to cause such persons to be medically examined and certified.

Additional precautions will be required, according to the character of the works. Thus the Associated Portland Cement Manufacturers, Ltd., have adopted the following notice, in addition to instructions somewhat similar to those given here:—

Regular inspection of kilns must be made on opening after being burnt off to see that they are safe for men to

* It should be their duty to gauge the cylinders (by means of a pressure gauge), whenever it has been used and see that they are adequately charged for future use.

work in. Under normal conditions the kiln is partly and sometimes entirely drawn before the chamber is cool enough to enter to clear for reloading, and inspection must cover safety, not only as to heat but as to gases. The eye in front of kiln and back eye of chamber must be opened when drawing is commenced, and entrance to chamber must be made cautiously. Should there be the slightest indication of gas, a paper torch must be thrown into the kiln and seen to burn out properly before work therein is commenced. If after several attempts it is clearly shown that a paper torch will not burn freely, the men must not be allowed to enter, and the matter must be at once reported to the manager. This applies more particularly where there is a kiln burning next to one that is being drawn, but in any case the dampers of the kiln being drawn must be down tight, and precautions taken generally to see that fumes from a burning kiln on the same flue cannot get back into a kiln in which men are at work, and this applies not only to the work of clearing or drawing, but to repair or any kind of work done in or about kilns.

In case of a kiln which has lain cold for a long period, all the above-named precautions must be observed, and, in addition, before men enter the pan or chamber, the drawing eye of the kiln must be opened, and thoroughly freed below so that the air may pass into the charge. Employees are especially warned against adopting the means employed by many persons ignorant of the first principles of resuscitation, viz., placing men on their faces with mouth over a hole in the ground. All such means are strictly forbidden. The administration of stimulants in any form is most dangerous, and is also strictly forbidden.

In towns where the public gas supply is largely charged with water gas, attention to gas fittings in factories and workshops becomes a matter of increased moment.

Respirators of the usual type designed to protect the wearer against inhalation of dust are of no avail as a protection against carbonic oxide poisoning.

The symptoms of carbonic oxide poisoning begin with throbbing of the blood vessels of the head, giddiness, palpitation of the heart, and weakness of the limbs. These become greatly aggravated after any exertion. Owing to their insidious onset and the cumulative effect of the gas the weakness of the limbs may come on without attracting notice, so that the person affected is unable to make good his escape.

Headache, anæmia, and defective nutrition may result from the long continued breathing of the gas in amount too small to produce immediate effects. Such symptoms may be caused by defective gas fittings in workrooms.

Remedies.—The appropriate remedies for poisoning by carbonic oxide are—fresh air, artificial breathing, administration of oxygen, and the application of warmth. They should be applied without any delay, and hence the importance of competent "first aid."

PATENTS.

Briquettes; Manufacture of — from coal, peat, and moor coal. J. Buss and C. Fohr. First Addition, dated Aug. 7, 1908 (under Int. Conv., Aug. 10, 1907) to Fr. Pat. 372,744, Dec. 17, 1906 (this J., 1907, 520).

THE process described in the main patent may be applied to the manufacture of briquettes from combustible materials which have previously been subjected to distillation, e.g., coke. Improvements are also claimed in the means for introducing steam into the mixing chamber, and a special scraper with curved arms is provided for expelling the mass from the lower end of the chamber.—A. S.

Briquettes; Binding agent [from sulphite-cellulose lyes] for the manufacture of —. Gewerkschaft Eduard. Fr. Pat. 392,898, Aug. 3, 1908. Under Int. Conv., March 11, 1908.

THE concentrated lye is converted into a gelatinous mass by heating with an acid, such as sulphuric acid, or with suitable salts, such as aluminium sulphate, and the product is mixed with an inert material such as coal dust,

infusorial earth, etc., to form a mass capable of being moulded. Tar or asphaltum may be added to the lye before the treatment with the acid or salt.—A. S.

Smokeless fuel; Distillation of coal for the production of a —. W. C. White, Sidecup. Eng. Pat. 28,692, Dec. 31, 1907.

BITUMINOUS coal, preferably small, is sprayed, before or after it is charged into retorts with a mixture in water of equal proportions of sodium chloride, sodium carbonate, and calcium chloride, the quantity of the mixture used being such as to contain about 2½ lb. of the salts per ton of coal. The coal is heated in retorts for 4 to 6 hours at a temperature not exceeding 450° C., a low pressure being maintained by a vacuum pump, until about half of the gas in the coal has been distilled. The fuel is suitable for domestic purposes.—A. T. L.

Coke quenching apparatus. Akt.-Ges. für Kohlendestillation, Gelsenkirchen-Buhlme, Germany. Eng. Pat. 18,110, Aug. 28, 1908. Under Int. Conv., Oct. 21, 1907.

THE apparatus, which is suitable for use with horizontal ovens, comprises two water-chambers, which, when brought into position before the oven, form continuations of the side walls of the retorts. The inner face of each water-chamber is perforated and the coke is sprayed with water as it passes between the chambers. The apparatus is mounted on wheels which run in rails of U-section sunk in the ground, and in order to present a smooth surface for the passage of the coke, the lower tie-bars connecting the water-chambers are bent so as to fill the channel rails in front of the retort. The space between the inner ends of the water-chambers and the face of the oven is closed by iron doors hinged to the water-chambers and secured to the tie-bars of the oven from the outside by wedges.—A. T. L.

Producer gas; Apparatus for the manufacture of —. L. C. Barker, Colchester. Eng. Pat. 26,644, Dec. 2, 1907.

THE object of the invention is to ensure that the body of the fuel through which the steam and air passes in the producer shall always be in a proper state of incandescence. The air and steam enter the producer through an opening the width of which is regulated by a damper; the width of the opening so formed, regulates the depth of the mass of incandescent fuel, as the air and steam traverse the producer horizontally and escape into a flue on the other side. The hearth of the producer is hollow and contains water which is vaporised, the steam so formed being either allowed to pass into the exit flue and mix with the escaping gas, thus assisting the deposition of tar in the scrubber, or being mixed with the incoming blast of air and steam. When the apparatus is supplying producer gas for a gas engine, the use of a vaporiser is also claimed, in which the water to be vaporised is admitted to an annular vaporising space surrounding the exhaust pipe of the engine, the flow being regulated by a valve in such a manner that water is admitted to the vaporiser each time the cylinder charge is exhausted.—E. F.

Gas producers. E. Jones, Perry Bar, and Kynoch, Ltd., Birmingham. Eng. Pat. 6495, Mar. 24, 1908.

THE object of the invention is to provide a float feed arrangement for automatically controlling the supply of water to the vaporiser of suction gas producers. The water is contained in three vessels, H, F, and D, and flows from one to the other in the order named, the flow in each case being regulated by a valve controlled by a float. The vessel, H, is a shallow pan, the bottom of which is formed by the top of the vaporiser. The air passes over this pan on its way to the producer, as indicated by the arrows. The producer-gas passes through the inner tube, B, of the vaporiser on its way to the scrubber, C. The second vessel holding water is formed by the outer tube of the vaporiser. From this it flows to the

third vessel, D, which is under the ash-pit, ensuring that the air which enters through the fire-grate, E, is charged with a large quantity of water-vapour. The amount of water in each of the three containing vessels is controlled automatically by the level of the water in it. Sometimes only the first and second controlling apparatus is used.—E. F.

Gas; Manufacture of —, and apparatus therefor. J. Hammond, Eastbourne, and J. Cash, Hove. Eng. Pat. 12,955, June 17, 1908.

THE process consists in the combustion of the outer surface of a mass of coal, accompanied by the destructive distillation of the internal mass, and the intermittent formation of water-gas from the coke produced. The apparatus is of the producer type. The coal is forced up a vertical conduit to the centre of a rotating annular stepped grate at the base of the producer-chamber. The walls of the producer-chamber are formed with vertical ribs or channels to facilitate the passage of air over the outer surface of the mass of coal. Above the producer-chamber is a fuel-chamber surrounded by an annular regenerator. The producer is provided with steam and air inlets below the grate. The working with twin producers is as follows: Both producers are blown with air until the outer parts of the mass of coal are carbonised. The products of combustion pass through the regenerators, and thence through the water-gas carburettor and superheater, or to a stack-pipe, and the gases distilled from the mass of coal, are drawn by exhausters through the fuel-chambers and are passed through the scrubbers. The air-blast is next stopped, and one of the producers is blown with steam. The outlet from the regenerator being closed, the steam is forced through the incandescent coke into the mass of fuel, and through the fuel-chamber; the gases then pass through the regenerator of the other producer, and through the fuel-chamber to the carburettor and superheater. The steam-blow is made in each producer in turn. Steam is used in excess, so that considerable quantities of ammonia and tar are obtained as by-products.—A. T. L.

Gas; Process of producing —. C. J. Greenstreet, Alton. Ill. U.S. Pat. 906,793, Dec. 15, 1908.

LIMESTONE or other mineral carbonate, and a carbonaceous substance are heated in a retort, and steam is injected during the heating. The carbonaceous substance may be the waste from the distillation of crude petroleum, and the illuminating and heating values of the gas may be increased by injecting oil with the steam.—A. T. L.

Gas producer. J. Maly, Dresden, Germany. U.S. Pat. 906,812, Dec. 15, 1908.

THE base of a gas producer is formed by a revolving annular water trough. A pyramidal grate is mounted

centrally in the water trough and revolves with it, the apex of the grate being eccentric to the axis of rotation. The interior of the grate is divided, by horizontal partitions, into a number of compartments with independent steam and air supplies. The uppermost compartment is provided with a perforated vertical partition, so that more steam is delivered at one side of the upper chamber than at the other.—A. T. L.

Gas; Apparatus for producing —. F. E. Fink, Cortland, Ohio. U.S. Pat. 907,110, Dec. 15, 1908.

A COKEING chamber is arranged above a producer chamber and connected thereto by a vertical neck, and a water-seal is arranged below the producer chamber. A vertical shaft with radial arms extends through the two chambers and the neck, and is rotated to stir the fuel. Air inlets are provided near the base of the coking chamber, and the tar and by-products are drawn off from the upper part of the coking chamber by a steam-jet. The tarry gases are delivered, with air if desired, through a series of conical deflectors, into the centre of the lower part of the producer chamber. Gas outlets are provided in the upper parts of the coking and producer chambers, and the gases from each chamber may be led away separately or through a single main.—A. T. L.

Gas producer. A. Bouvier. First Addition, dated July 30, 1908, to Fr. Pat. 376,201, March 28, 1907.

THE low-grade gas from a producer is passed through a combined washer, scrubber, and dryer as described in the main patent. This portion of the apparatus consists essentially of a well containing water, into which the gas is delivered, surmounted by a chamber in which horizontal turbine- or fan-wheels, mounted on a central vertical shaft, are caused to rotate by the suction of the gas-engine. On the upper portion of the shaft a series of perforated plates are mounted in order to retain the moisture carried by the gas. Owing to the jets of water playing on the fan-wheels and the deposition of tar and dust on them, it is difficult to obtain uniform rotation by means of the suction of the gas-engine alone. According to the present addition, therefore, a horizontal water-wheel is fixed on the shaft above the fan-wheels, and is caused to rotate by jets of water introduced tangentially, the water then falling and serving to wash the gas.—A. S.

Retort furnaces; Vertical — for the manufacture of illuminating gas. C. Bolz. Fr. Pat. 393,081, July 11, 1908.

A NUMBER of vertical retorts are fixed in rows in a chamber through which the heating gases pass in an upward zigzag path formed by horizontal baffles. A gas-producer is arranged beneath each retort-chamber, and regenerators above the level of the operating platform and between adjacent retort-chambers in the length of the furnace. The producer gas and the hot air from the regenerators are admitted to each retort-chamber at both sides, through apertures opposite to the spaces between the rows of retorts; or in an alternative construction, the heating gases are admitted to the retort-chamber through apertures in a central flue running between two rows of retorts, the apertures being opposite to the spaces between the retorts. The heating gases pass from the retort-chambers to the regenerators, and finally escape through short shafts built directly above the regenerators. The retort-chambers and the superstructure are supported on columns independently of the lower part of the structure. The arrangement of the regenerators between the retort-chambers, instead of below them, enables a water-gas generator to be placed beneath each retort-chamber, and the hot coke from the retorts can be discharged directly into the water-gas generator; a conveyor is also placed between the gas producers and the water-gas generators. In charging the retorts, the coal is discharged from a hopper on to an inclined surface, so that the larger pieces rebound and are thrown towards the sides of the retort and afford a free passage for the gases formed during the distillation.—A. T. L.

Oil-gas; Apparatus for the production of ——. P. Suckow and Comp. Inhaber R. Meyer. Ger. Pat. 202,579, June 5, 1907.

THE retorts in which the oil-gas is produced, are heated externally at the bottom. They are of rectangular cross-section and are narrower at the bottom than at the top. The bottom edges of the retort are rounded, and along the middle of the floor of the retort there is a projection of triangular prismatic form jutting into the gas-producing space.—A. S.

Washer-scrubbers for the purification of cool- and other gases. Kirkham, Hulett and Chandler, Ltd., and S. Hersey. London. Eng. Pat. 28,387, Dec. 24, 1907.

THE patent relates to washer-scrubbers comprising a series of compartments in which washing devices, such as sets of parallel discs, are rotated. The washing devices in each pair of adjacent chambers, are mounted on a central hollow boss, which extends through the dividing wall between the compartments. The gases entering the first compartment of the scrubber through an opening in the casing, pass through the washing device from the circumference towards the centre of the discs, and then through the hollow boss to the centre of the washing device in the next compartment. A packing ring is provided to prevent the passage of gas from one compartment to the next outside the hollow boss. The washing discs are built up of bundles of sector-shaped plates held in position by bolts, and the plates in each bundle are connected together by an independent bolt near the outer edge, by means of which the bundles of plates can be lifted out through manholes in the casing of the scrubber.—A. T. L.

Coal gas or water gas; Methods of scrubbing, cooling, or otherwise treating ——. J. S. McIlhenny, Washington, U.S.A. Eng. Pat. 8729, April 21, 1908.

CONDENSERS or coolers and scrubbers are arranged alternately in a series, and the gas is passed through in the opposite direction to the cooling medium. The condensers successively increase in size, and the scrubbers decrease, from the end at which the gas enters. The speed of the gas is thus successively diminished in its passage through the condensers and increased in its passage through the scrubbers. The speed of the cooling medium may be successively increased in its passage through the condensers. The condensers and scrubbers are so connected that the cooling medium may be used for scrubbing the gas after it has been employed in its particular stage of the cooling.—A. S.

Incandescent bodies for electric lamps; Manufacture of ——. F. J. Planchon, Paris. Eng. Pat. 4956, Mar. 4, 1908.

AN aqueous or alkaline solution of a carbohydrate is mixed with an alkaline solution of an oxygenated compound of tungsten or molybdenum, such as tungstic acid, and the mixture is poured into dilute acid. A compound of tungstic acid and the carbohydrate is precipitated, which contains from 68 per cent. of tungstic acid if gum arabic be used, or up to 72 or 76 per cent. if cellulose be used. This compound, either alone or mixed with its components or with other substances, is formed into a plastic mass with water or with alkali, and made into filaments in the usual manner.—A. T. L.

Incandescent electric lamps, heaters, and the like; Incandescent or heating bodies containing or consisting of zirconium for ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, New York. Eng. Pat. 5415, Mar. 10, 1908.

FILAMENTS or other conductors are made from zirconium oxalate with just sufficient finely-divided carbon to effect reduction to metallic zirconium on heating to the necessary temperature, without leaving any residual carbon. No binding material is necessary since the zirconium

oxalate itself forms a tenacious paste, which can be squirted. It may be prepared by the precipitation of hot zirconium nitrate solution with ammonium oxalate, and has a smooth, even, gelatinous texture, resembling that of starch paste. The heat treatment necessary for the reduction, may be carried out in an inert atmosphere or in a vacuum, and the furnace described in Eng. Pat. 29,809 of 1904 (this J., 1905, 976) may be used, though it is better to replace the graphite heater there described by one made of tungsten. The method may also be applied to the production of conductors consisting of alloys of zirconium with other metals. The use of finely-divided reducing agents other than carbon, is also claimed.—E. F.

Electric incandescence bodies of tungsten; Manufacture of ——. Siemens und Halske Akt.-Ges., Berlin. Eng. Pat. 19,311, Sept. 14, 1908. Under Int. Conv., Sept. 26, 1907.

NICKEL tungstate is reduced, for example by heating in hydrogen, and the resulting ductile alloy or mixture of tungsten and nickel is heated to volatilise the nickel. In carrying out the process, nickel tungstate is mixed with tungsten powder, or with a reducible compound such as tungstic acid, or with colloidal tungsten compounds such as are described in Eng. Pats. 11,716 and 16,489 of 1907, and the Second Addition to Fr. Pat. 378,743 (this J., 1907, 1192; 1908, 496, 1104), and the mixture is formed into rods or filaments. The mixture should contain nickel and tungsten in proportions which will give an alloy containing 5 to 20 per cent., and preferably 12 per cent., of nickel. A rod 0.6 mm. thick would be heated in a current of hydrogen at 1650° C. for 50 seconds, but the best working conditions are different in different cases. After reduction, the filaments are subjected to a drawing and rolling process, and then heated electrically in a vacuum.—A. T. L.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleum; New colour-reaction of ——. C. Arragon. Chem.-Zeit., 1909, 33, 20—21.

AMERICAN petroleum, when shaken vigorously with an equal volume of nitric acid (free from nitrous acid), of

sp. gr. 1.4, becomes coloured bright violet, whilst the acid turns yellow. Austrian, Bohemian, Galician, or Russian petroleum when similarly treated is coloured yellow, and the acid becomes brown. Mixtures of American oil with the other oils strike the violet colour in the first instance, but after a few seconds this vanishes and the yellow colour appears and remains. In this way, for example, 10 per cent. of Austrian oil can be detected in admixture with American oil.—J. T. D.

Mineral lubricating oils; New values in the analysis of —, R. Kissling. Chem. Rev. Fett- u. Harz-Ind., 1909, 16, 3—5.

In a previous communication (this J., 1908, 1053) the author described a method of testing the behaviour of machine oils under conditions of continual heating, such as they would encounter in, e.g., turbines. The examples given before included only one kind of heavy Russian machine oil, and the following results are therefore quoted:—

Russian machine oils.	Sp. gr. at 15° C.	Viscosity (Engler).	Flashing point ° C.	Ignition point ° C.	Before heating.		After heating.		Total of Tar- forming and coke- forming values.
					Tar value.		Tar- forming value.	Coke- forming value.	
Cylinder oil, Nobel 00.....	0.912	13.00 at 50° C.	240	280	0.168	0.468	0.355	0.823	
Do.....	0.913	14.00 at 50° C.	240	280	0.266	0.501	0.484	0.985	
Heavy machine oil, Nobel C.....	0.909	7.00 at 50° C.	215	240	0.239	0.458	0.782	1.240	
Spindle oil.....	0.892	6.80 at 25° C.	175	200	0.213	0.474	0.753	1.227	

From these figures it appears that as regards the amount of tar they contain and their tar-forming and coke-forming values, Russian lubricating oils are inferior to Pennsylvania, but better than Texas oils.—C. A. M.

Paraffin oil; Note on the iodine value of —, J. Dreyfus. J. Amer. Leather Chem. Assoc., 1908, 3, 394.

To obtain constant results fully 80 per cent. of the amount of the Hanus iodine solution added, should be in excess, and at least 8 hours should be given for the absorption of the iodine. The Hübl-Waller method is of no use.

—H. G. B.

Colloidal solutions of calcium soaps in heavy mineral oils. Holde. See XII.

PATENTS.

Ammonia from gas-liquor; Apparatus for separating —, Berlin-Anhaltische Maschinenbau A.-G. Ger. Pat. 204,858, Jan. 12, 1907.

THE patent relates to a process for utilising the heat of the gases from the gas-retort furnace for distilling ammonia from the gas-liquor. The ammonia still is mounted above the flue through which the furnace-gases pass on their way to the chimney. The lowest compartment of the ammonia still is divided into upper and lower sections, connected by vertical tubes passing through the upper bend of an inverted U-shaped pipe, the limbs of which open into the furnace-gas flue below. The furnace-gases pass through this pipe and serve to distil off the ammonia, and a movable damper is provided in the flue between the two limbs of the inverted U-shaped pipe, so that the proportion of the gases passing through this pipe can be regulated as desired.—A. S.

Sodium compound of indene; Process for preparing —, Ges. f. Teerverwerthung. Ger. Pat. 205,465, Feb. 12, 1908.

A compound of indene with sodium is obtained by the action of sodium amide, or sodium in presence of dry ammonia, on indene or hydrocarbon mixtures containing indene. For example, 500 kilos. of coal tar distillate,

b. pt. 175—185° C., freed from phenols and bases, are heated with 40 kilos. of sodium amide, with agitation, for 1½ hours at 100—105° C.; when cool, the supernatant layer of hydrocarbons is removed, and the sodium compound of indene is recovered from the hydrocarbons in which it is in solution by heating at 110°—130° C. under a pressure of 20—30 mm.—T. F. B.

Decomposition of indifferent chemical substances (mineral oils, etc.) and the transformation of their elements into products of technical value; Process and apparatus for the —, J. Tanne and G. Oberländer. Fr. Pat. 393,047, Aug. 8, 1908.

THE material, (mineral oil), to be treated is placed in a closed tank provided with a vertical extension at the top, closed by a movable cover. A coil formed of conducting material and covered with asbestos or other similar non-conducting body is suspended in the liquid. That portion of the coil which is immersed, has a large number of very fine perforations. The coil is isolated from the tank itself

by porcelain rings and is heated by passing a current of electricity through it, the temperature being controlled by thermometers in contact with the projecting ends of the coil. Air, chlorine, or any other suitable gas is passed into the coil at each end, from pipes connected to the coil by insulating rings, and after becoming heated passes through the perforations. The liquid in the tank is absorbed by the porous covering of the coil, and the gas passing through the latter is forced into intimate contact with the absorbed liquid. The result of this forced intimate contact is stated to be the elimination of hydrogen and the formation of bodies like solid paraffin and ozokerite. —W. H. C.

Hydrocarbon oils and similar substances; Process for converting — into light oil or petrol. J. Noad and E. J. Townsend. Fr. Pat. 393,433, Aug. 18, 1908. Under Int. Conv., June 27, 1908.

THE vapour of the oil, mixed with steam, is brought into contact with a large surface of iron heated to redness in the absence of air, the resulting vapours are condensed, and the light oil separated by distillation. The light oil is suitable for use in internal-combustion engines. The residues from the distillation are again submitted to the process. The process may be carried out by leading the oil and water, in about equal quantities, in continuous streams into one end of a chamber packed with iron turnings and heated to about 480° C. The fixed gases formed during the process may be used to heat the chamber. The iron appears to act as a catalytic agent, and there is no deposit of carbon.—A. T. L.

Petroleum and its distillates; Apparatus for ionising —, D. Martini, London. U.S. Pat. 908,297, Dec. 29, 1908.

SEE Eng. Pat. 16,432 of 1907; this J., 1908, 890.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Trisazo-dyestuffs from resorcinol. F. Muhlert. Z. angew. Chem., 1908, 21, 2611—2612. (Compare Paul, this J., 1908, 1013.)

TRISAZO-DYESTUFFS can be prepared from resorcinol by treating it with three molecules of a diazo-compound,

or by the action of one molecule of a diazo-compound on a resorcinol disazo-dyestuff. The dyestuff from resorcinol and three molecules of diazobenzenesulphonic acid is easily soluble and gives brownish-orange shades on chrome-mordanted wool, which are, however, not fast to milling. The pale brown dyestuff produced by using three molecules of diazotised naphthionic acid is very soluble and that from three molecules of diazotised Safranine is a very soluble blue compound giving on tannin-mordanted cotton, tints which are redder than Indoin Blue but not so fast to light.—J. C. C.

Dyestuffs in solution; Capillary rise of —. L. Pelet-Jolivet and C. Jess. *Z. Chem. Ind. Kolloide*, 1908, 3, 275—280.

STRIPS of filter-paper, 8 cm. wide and 30 cm. long, were immersed to a depth of 15 mm. in 50 c.c. of dyestuff solution and the height to which both the dyestuff and the water rose in 3 hours was noted. Tables are given showing the results for many commercial dyestuffs, both alone and in the presence of varying quantities of electrolytes. It was found that the acid wool dyestuffs were characterised by a large rise of 100 to 200 mm. The basic and direct cotton dyestuffs showed small rises of 8 to 105 mm. The phthalein dyestuffs gave a medium rise of 60 to 150 mm. It thus appears that the stronger the adsorption by the cellulose, the smaller the rise. In the case of those dyestuffs which are not adsorbed, the rise is comparatively independent of the concentration of the solution, whilst the adsorbed dyestuffs rise to a greater extent from stronger solutions. An exception to this rule is found in the case of specially viscous adsorbed colours such as Carbazol Yellow, and is probably due to the pores of the paper being stopped up. Dyestuffs of the same class vary considerably in behaviour, and the capillary rise decreases with increasing molecular weight; in the case of the basic dyestuffs and Rhodamines, it increases with decreasing basicity. Those dyestuffs the solutions of which show colloidal characters under the ultramicroscope show the smallest capillary rise. In the case of Methylene Blue the rise of both dyestuff and water is increased by hydrochloric acid, which retards dyeing, and decreased by sodium hydroxide, which promotes it. In the case of Crystal Ponceau, addition of hydrochloric acid, which promotes fixation on the fibre, decreases the capillary rise, but this is not lessened by the addition of sodium hydroxide, sodium sulphate, or sodium phosphate, which is contrary to what might be expected. Experiments were also made on the capillary rise in strips of linen, silk, and wool. Linen was found to behave in a similar manner to filter-paper or cotton, though it shows less affinity than these for direct cotton colours. Wool and silk show much more adsorptive power than the vegetable fibres.—E. F.

PATENTS.

Anthracene derivatives; Manufacture of —. P. A. Newton, London. From Farbenfabrik vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 1822, Jan. 27, 1908.

HALOGEN substituted anthraquinones can be obtained by treating anthraquinonesulphonic acids with halogens or compounds capable of splitting off halogens. The sulphonic acid groups are replaced by halogen atoms. Starting from anthraquinonedisulphonic acids the process proceeds in steps, the hitherto unknown halogen substituted monosulphonic acids being first produced. Example—A current of chlorine is passed into a mixture, heated to 100° C., of 20 parts of the potassium salt of anthraquinone-1-sulphonic acid, 1500 parts of water, and 60 parts of hydrochloric acid (20° B.). The mixture is filtered and the precipitate washed and dried.—P. F. C.

Flavopurpurin; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 205,097, Dec. 12, 1907.

ANTHRAFLAVIC acid or salts of anthraquinone-2,6-disulphonic acid are converted into flavopurpurin by heating

with a large excess of moderately concentrated (30—50 per cent.) alkali hydroxide solutions, at temperatures of about 200° C., with or without addition of oxidising agents. The temperature need not be carried above 200° C. if the amount of alkali hydroxide is at least 25 times the amount of anthraflavic acid used, or at least 12 times that of the anthraquinonedisulphonate.—T. F. B.

Sulphurised vat dyestuffs of the anthracene series; Manufacture of —. O. Imray, London. From Soc. of Chemical Industry, Basle, Switzerland. Eng. Pat. 13,057, June 18, 1908.

By heating an amino-, alkylamino-, arylamino-, acylamino- or nitro-derivative of 2-methylantraquinone or a substitution product of such a derivative, with sulphur at a comparatively high temperature, new sulphurised products are obtained which are insoluble in alkali sulphide, but can be made into a vat with the aid of alkali hydrosulphite solution; the vats thus obtained dye cotton directly without a mordant in grey, yellowish-brown, and violet shades of excellent fastness. Example:—A mixture of 60 parts of sulphur with 20 parts of 1-amino-2-methylantraquinone is heated to 240—280° C., until the evolution of hydrogen sulphide has ceased. The cooled mass is finely powdered and the excess of sulphur is extracted with carbon bisulphide or sodium sulphide solution. The purified dyestuff yields a brown vat with hydrosulphite from which cotton is dyed intense brown tints.—P. F. C.

Leuco-1,4-diaryldihydrazinoanthraquinones or their oxidation products; Preparation of —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 204,411, Aug. 9, 1907.

EQUAL parts of leucoquinizarin and phenylhydrazine are heated at 100° C., under a reflux condenser, in presence of alcohol or other solvent, for one hour, or until the leuco-compound has disappeared. Leuco-1,4-diphenylhydrazinoanthraquinone is thus obtained, and is purified by crystallisation. Analogous compounds are obtained from leuco-tri- and -tetrahydroxyanthraquinones, and also by using arylhydrazinesulphonic acids. Reddish-brown dyestuffs are obtained by passing air into caustic alkali solutions of the condensation products.—T. F. B.

4-Amino-2-nitrobenzoic acid; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 204,884, July 2, 1907.

2,4-DINITROBENZOIC acid may be reduced to 4-amino-2-nitrobenzoic acid by means of alkali sulphide, the presence of alkali or substances with alkaline reaction being avoided. 21.2 parts of the dinitrobenzoic acid are introduced into a solution of 33 parts of sodium sulphide in 40 times its weight of water at 60° C.; the mixture is heated at 90° C. for three hours, when the solution is rendered feebly acid. The new aminonitrobenzoic acid, mixed with sulphur, is precipitated, and is purified by crystallisation from water; it melts at 234—235° C. with decomposition, and forms an easily soluble diazo compound.—T. F. B.

Anthrapyrimidones; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 205,035, Nov. 5, 1907.

By condensation of urethanes with α -aminoanthraquinones or α -alkylaminoanthraquinones, with the aid of heat, and preferably in presence of zinc chloride or other condensing agent, anthrapyrimidones of the general formula,

are formed. They possess both feeble acid and feeble basic properties, and are either applicable as dyestuffs or for the preparation of dyestuffs.—T. F. B.

Dyestuffs of the anthracene series; Process for preparing blue —, Farbwerke vorm. Meister, Lucius, and Brüning. Ger. Pat. 205,006, Nov. 30, 1907.

DYESTUFFS which dye wool from acid baths in pure blue shades, fast to alkalis, are obtained by heating leucoquinizarin-5-sulphonic acid with two molecular proportions of monoalkylamines; the resulting products are 1,4-di-monoalkylaminoanthraquinone-5-sulphonic acids. —T. F. B.

α -Isatinanilide or its homologues and sulphurous acid; Preparation of compounds of —, C. Stephan and A. Rahtjen. Ger. Pat. 204,478, Oct. 2, 1907.

COMPOUNDS of α -isatinanilide or its homologues with sulphurous acid are obtained (1) by adding a dilute acid solution of α -isatinanilide or a dilute acid suspension of its salts to a solution of sulphurous acid, a bisulphite, or thiosulphate; (2) by passing sulphur dioxide into the libite solution or suspension of the anilide. The quantity of sulphurous acid used in each case should be equivalent to that of the α -isatinanilide. —T. F. B.

α -Isatinanilide and its homologues; Manufacture of compounds of — by means of sulphurous acid. — C. Stephan and A. Rahtjen. Fr. Pat. 393,085, July 16, 1908. Under Int. Conv., Oct. 1, 1907.

Trisazo dyestuffs and their dycings; Process for preparing green —, L. Cassella und Co. Ger. Pat. 204,707, Nov. 12, 1907.

GREEN trisazo dyestuffs are obtained by combining the intermediate product from tetrazodiphenyl and salicylic or *o*-cresotinic acid, in acid solution, with 1,8-amino-naphthol-4,6-disulphonic acid, the disazo dyestuffs thus obtained being combined with diazo compounds either in substance or on the fibre, in alkaline solution. The dycings obtained are intense in shade, and fast to washing and light. —T. F. B.

Trisazo dyestuffs; Manufacture of —, R. B. Ransford, Upper Norwood. From L. Cassella und Co., Frankfurt on Maine, Germany. Eng. Pat. 26,811, Dec. 4, 1907.

SEE Ger. Pat. 204,707 of 1907; preceding. —T. F. B.

**p*-Phenylenediamine; Process for preparing* —, Act.-Ges. f. Anilinfabr. Ger. Pat. 201,848, Feb. 14, 1908. Addition to Ger. Pat. 202,170, Dec. 7, 1907 (see this J., 1908, 1147).

p-CHLOROANILINE is converted into *p*-phenylenediamine by heating it with aqueous ammonia in presence of copper salts; the ammonia and excess of *p*-chloroaniline are removed by means of steam, and the residue is evaporated to the crystallising point; any remaining *p*-chloroaniline is extracted from the product by means of petroleum spirit. —T. F. B.

**p*-Phenylenediaminemonosulphonic acid; Process for preparing* —, Act.-Ges. f. Anilinfabr. Ger. Pat. 204,972, Jan. 24, 1908. Addition to Ger. Pat. 202,564, Nov. 15, 1907, (see this J., 1908, 1147).

p-CHLOROANILINE-*m*-SULPHONIC acid is converted into *p*-phenylenediaminesulphonic acid by heating under pressure with ammonia in presence of copper salts. —T. F. B.

Vat dyestuffs containing sulphur; Process for preparing —, Badische Anilin und Soda Fabrik. Ger. Pat. 205,002, Nov. 3, 1906.

Dihalogen derivatives of 3-ketodihydro-(1)-thionaphthene are obtained by the action of halogens on 3-oxy-(1)-thionaphthene or its homologues or derivatives; these combine with 3-oxy-(1)-thionaphthene, indoxyl, halogenated indoxyls, or the homologues or derivatives of these

compounds, to form vat-dyeing (indigoid) dyestuffs. The dyestuff from 2-dihydro-3-ketodihydrothionaphthene and 3-oxy-(1)-thionaphthene is not included in the claim, being more readily obtained by heating the product resulting from the action of halogens on oxythionaphthene. —T. F. B.

1,3-Diaminoanthraquinone; Process for preparing derivatives of —, Badische Anilin und Soda Fabrik. Ger. Pat. 205,036, Aug. 14, 1907.

DIAMINO-BENZOYLEN-*benzoic* acid derivatives, in which the amino-groups are in the *meta*-position to one another and to the carbonyl group, are readily converted into 1,3-diaminoanthraquinone derivatives by heating either alone or in presence of acids, such as acetic acid; any derivatives of the diamino-benzoylbenzoic acid which have an *ortho*-position to the carbonyl group free in each nucleus undergo the same change. The preparation of triaminomethyl-anthraquinone, 1,3-diamino-2-methylanthraquinone, and 1,3-diamino-2-methoxyanthraquinone is described in the specification. —T. F. B.

**p*-Aminodiazobenzene and its derivatives; Process for preparing* —, Badische Anilin und Soda Fabrik. Ger. Pat. 205,037, Sept. 24, 1907.

THE diazo derivatives of acetyl-*p*-phenylenediamines or their homologues are converted into *p*-aminodiazobenzene derivatives by heating with dilute mineral acids, the acetyl group being completely removed, for example, after heating for an hour at 70° C. without appreciable decomposition of the diazonium group. 15 parts of acetyl-*p*-phenylenediamine are diazotised by means of 7 parts of sodium nitrite and 30 parts of hydrochloric acid (sp. gr. 1.16), and the solution, after the addition of 30 parts of hydrochloric acid, is heated at 70° C. for one hour. The solution of *p*-aminodiazobenzene chloride thus obtained reacts slowly with azo components, no dyestuff being at first produced, for instance, with an alkaline solution of β -naphtholdisulphonic acid R in the cold; by warming, however, or after long standing, a violet-red dyestuff is obtained. —T. F. B.

Sulphur [sulphide] dyestuffs; Manufacture of new —, P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 5485, March 11, 1908.

SEE Fr. Pat. 388,539 of 1908; this J., 1908, 895. —T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Electrolytic bleaching process; Preparation of alkali hypochlorites, and the —, F. J. G. Beltzer. Z. angew. Chem., 1909, 22, 8—14.

IN the production of sodium hypochlorite, salt solutions of 4°—16° B. (sp. gr. 1.029—1.277) are electrolysed, the more concentrated solutions being preferably employed, as the conductivity of the solution increases with the concentration. An amount of electricity corresponding to about 7 kilowatts is required in practice to produce 1 kilo. of available chlorine, and the cost will vary with the source of the power (steam, gas, water) employed in producing the current. Under the most expensive conditions (use of steam power and "brine") the cost of chlorine would be about 0.35 franc, whereas by using water power and sea-water, the cost would be no more than 0.05 franc per kilo. of chlorine. The electrolyser of the Electrolytic Bleaching Co., Ltd. (with platinum electrodes) is shortly described; in this, the salt solution (of carefully regulated concentration and rate of flow) circulates between the electrodes, and the hypochlorite solution passes direct to the bleaching tanks or to reservoirs, as desired. A 15 per cent. salt solution yields a hypochlorite solution

containing 30 grms. of available chlorine per litre and 1170 litres will contain therefore 35 kilos. of available chlorine, or a quantity sufficient to bleach 5000 kilos. of cotton. When the electrolysed solution is to be passed direct to the bleaching tanks, it is convenient to use a salt solution of 1.5 per cent. strength, which yields a hypochlorite liquor containing 3 grms. of available chlorine per litre. In summing up the advantages of the electrolytic over the ordinary bleaching process, the author draws attention to the fact that the electrolytic hypochlorite is neutral in reaction, whereas the solution prepared by mixing solutions of bleaching powder and sodium carbonate (or by saturating caustic soda with chlorine, etc.) is always alkaline; the consequence is that solutions prepared in these latter ways do not give up their chlorine so readily to the material to be bleached, and to get the full effect from them, they have to be warmed or acidified. It has been found that a quantity of electrolytic hypochlorite containing 0.8 grm. of chlorine, is equal to a quantity of ordinary hypochlorite containing 1 grm. of chlorine. In comparison with bleaching powder, it is evident that sodium hypochlorite is much safer and simpler to use, and not only is the bleach whiter and more permanent—not liable to become yellow—but there is no risk of damage from particles of undissolved powder producing intense local action, and the goods remain soft and free from harshness. The author discusses the arrangements required for the electrolytic bleaching of 5000 kilos. of cotton per day of 10 hours, and compares the cost of production of electrolytic chlorine, with that obtainable from ordinary sodium hypochlorite and from bleaching powder.—F. M.

Paranitraniline-red; Formation of —. M. Prud'homme and A. Colin. Rev. Gen. Mat. Col., 1909, 13, 1—3.

THE fact that a solution of diazotised *p*-nitraniline containing acetic acid and sodium acetate gives a bluer and fuller shade of Para-red than one containing only hydrochloric acid has been attributed by Goldschmidt and later by Lichtenstein (this J., 1908, 976) to the difference in the concentration of hydrogen ions in the two cases. This is considered by the present authors to be a statement of fact but not an explanation, and they have therefore carried out experiments on the action of the ions Cl' and $\text{C}_2\text{H}_3\text{O}_2'$ (which are present in the two cases referred to) on the sodium naphtholate. Cotton padded with sodium naphtholate and then dried was dipped into distilled water and into the following solutions: dilute hydrochloric acid, dilute acetic acid, acetic acid and sodium acetate, sodium acetate. The cloth was then developed and the tints of Para-red compared. The following are the conclusions drawn: In the instantaneous formation of Para-red the free acid exerts an action proportional to the ionic concentration and liberates naphthol. If, other things being equal, the ionic concentration attains a suitable value, the amount of naphthol liberated will be slight. The thin layer which it forms on the fibre can exercise a protective action on the sodium naphtholate and prevent it from diffusing. If the ionic concentration is excessive, too large a proportion of naphthol is precipitated and as this combines indifferently with the diazo-compound, the intensity of the red produced is decreased. The diffusion and solution of the sodium naphtholate is important: this is greatest in the presence of pure water and varies with the nature of the acid and of the salts present. These can act directly in hindering the diffusion of the naphtholate, but they can also modify the degree of ionisation of the diazo-salt if they give rise to the same kind of ion when dissolved.—J. C. C.

Indian indigenous dyes; Experiments with — in comparison with synthetic products. U.S. Cons. Reps., Dec., 1908. [T.R.]

MR. E. R. WATSON, connected with the Asiatic Society of Bengal, has been experimenting with dyes, both indigenous and synthetic, and appears to demonstrate the superiority of the former over the latter so fully and clearly that it would seem the contention in favour of the latter would cease. Mr. Watson experimented with ten vegetable dyes,

viz., turmeric, or haldi (*Curcuma longa*); safflower, or kusum (*Carthamus tinctorius*); spanwood, or bakam (*Cesalpinia sappan*); palas (*Butea frondosa*); annatto, Orleans, or lakkam (*Bixa orellana*); majisto (*Rubia cordifolia*); kamala (*Mallotus philippinensis*); singher or harsinghar (*Nyctanthes arbor tristis*); jackwood, jack, or kanthal (*Artocarpus integrifolia*), and lac dye.

He followed the native methods of dyeing, and had no occasion to resort to any European as opposed to Indian method. He used silk cloth purchased from the Rij-bahi diamond jubilee industrial schools, and his success was greater than in the case of experiments in dyeing cotton fabrics. The conclusions he arrives at are that the indigenous dyes of Bengal are considerably more useful for dyeing on silk than for cotton dyeing, and that the dyeings obtained are frequently considerably faster on silk than on cotton. This, taken in conjunction with the fact that many of the commonly used synthetic dyes do not give fast dyeings on silk, causes the indigenous dyes to compare much more favourably with their synthetic adversaries in this field than was the case in that of cotton dyeing. He says:—

"The shades obtained from bakam on a tannin-iron mordant from majisto, from lac, kamala and jackwood, may be said to exhibit good fastness, since in no respect does any one of these dyeings come lower than III. in the scale. Thus of 10 dyestuffs examined, 3 have yielded dyeings which may be characterised as good average goods. Of the 12 synthetic dyestuffs used for comparison only 4, viz., alizarin, primuline, chrysophenine and magdala red are capable of yielding dyeings which may by the same criterion be similarly characterised."

The author's work would lead him to form a somewhat higher opinion of the value of the kamala as a silk dye than that apparently formed of it by A. G. Perkin (this J., 1895, 460). The dyeings with lac proved to be faster to soaping even than the synthetic dyes which were fastest in this respect. In fact, the general fastness of lac dyeings made it appear to me a matter of surprise that this material has been so completely superseded by synthetic dyes, the more so as it is necessarily obtained as a by-product in the purification of lac, a material for which there is an ever rapidly increasing demand.

PATENTS.

Artificial threads; Treatment of —. P. Follet and G. Ditzler, Verviers, Belgium. Eng. Pat. 21,255, Oct. 8, 1908.

SUPPORTS, *h*, on a frame, *a*, carry spindles, *e*, on which are mounted cylinders, *d*, rotating in troughs, *c*. The spindles, cylinders, and troughs can be moved along the brackets, *b*, so as to occupy the positions indicated in both the full and the dotted lines. The cylinders are rotated by a vari-

able gearing and when in movement carry on their surfaces thin coatings of the liquid contained in the troughs. Below the lower cylinder, *d*, is arranged a receptacle, *f*, into which spinning nozzles, *g*, force a solution of cellulose or other similar substance in an ammoniacal solution of a suitable metallic oxide or salt. The receptacle, *f*, contains a coagulating bath containing 15–20 per cent. of acid. The troughs, *e*, contain similar baths, the proportion of acid in which may decrease from the lower to the higher troughs until the highest contains only water, in which a spool, *h*, rotates, on which the thread is wound. On leaving the nozzle, *g*, the thread passes quickly through the bath contained in the receptacle, *f*, and is therefore only coagulated on its outside. It then passes on to and over the cylinders, *d*, and is thereby submitted to a tension which varies with the angle formed by the thread passing over the different cylinders. By making the cylinders, *d*, rotate at different speeds, the thread can be gradually stretched so long as its interior remains liquid. By this means threads of any desired degree of fineness can be obtained.—P. F. C.

Artificial silk and hair: Process for the preparation of —. A. Lœueur. Fr. Pats. 392,868 and 392,869, Oct. 8, 1907.

CELLULOSE is dissolved in an ammoniacal solution of cupric hydroxide and the resulting solution is forced through a capillary tube into a coagulating bath under constant pressure. The bath is maintained at a temperature of 27–35° C. and consists of a mixture of equal parts of a solution containing 44–49 per cent. of sodium hydroxide and a solution containing 23–28 per cent. of anhydrous sodium carbonate. A rather weaker bath is employed for artificial hair. After spinning, the thread is wound on a bobbin, and plunged into a second coagulating bath containing in solution as much anhydrous sodium carbonate as the first bath but much less sodium hydroxide. The copper and ammonia which remain in the product are eliminated by a passage through a dilute solution of sodium bisulphate to which 1–4 per cent. of free acid has been added. The process is completed by washing, soaping, if necessary, and finally drying the product.—P. F. C.

Dye jiggers or dyeing apparatus. F. Shaw and Whitefield Velvet and Cord Dyeing Co., Ltd., Whitefield, Lancs. Eng. Pat. 4295, Feb. 26, 1908.

THE invention consists in the use in combination with the dye-vat of a displacer arranged inside the vat which displaces the dye liquor over a greater area and consequently subjects the pieces to a longer immersion. If the dye-vat be circular, the displacing roller has a circular cross-section, whilst if the vat be angular, the displacer is of corresponding contour and rollers are arranged at points along its surface. The piece under operation passes from one roller of the jigger, under the displacer, to the other roller. The surface of the displacing device may be fluted to allow the dye-liquor to saturate the material more easily.—P. F. C.

Dyestuff preparations for dyeing: Direct cotton —. Read Holliday and Sons, Ltd., J. Turner, and H. Dean, Huddersfield. Eng. Pat. 7552, April 6, 1908.

By mixing together the free colour acids or acid salts of certain direct cotton dyestuffs, shades are produced which are superior to those obtained by using the dyestuffs as their sodium or ammonium salts. Dyestuffs which are suitable for this purpose, are sulphonated mono-, di-, or tri-beta-naphthylated rosaniline and the blue and violet tetrazo dyestuffs from benzidine, toluidine, diamididine, or other similar para-diamines.—P. F. C.

Variegated colour effects upon fabrics; Process for obtaining —. J. Hindley, Stockport. Eng. Pat. 10,922, May 20, 1908.

THE fabric is laid out and drawn up from its flat position into something approximating to the form of a cone at those places where a variegated colour effect is desired.

Yarn or tape is then tightly tied round each cone in two or more places, so as to produce a "scrumpled" effect and the whole fabric is dyed. The fastenings are then untied retied so as to produce a different "scrumpled" effect, and the fabric is again dyed with a different dyestuff. Before beginning the final dyeing which is to give the ground colour to the whole fabric, that part of the cone which lies between the fastenings is over-wrapped to prevent it from coming in contact with the dye-liquor. A modification of this process consists in knotting the fabric, as described, dyeing it, then re-knotting it one or more times and dyeing it with a different dyestuff each time.—P. F. C.

Dyeing apparatus. J. Friedrichs, Woonsocket, R.I. U.S. Pat. 907,229, Dec. 22, 1908.

EACH of a number of conical holes pierced in the floor of a dye-vat is connected on its under side with an suction pipe leading to a pump and on its upper side with an upright perforated spray tube arranged within a cage having perforated walls. A second pipe leading from the pump is disposed so as to deliver into the upper part of the vat. Means are provided for lifting the cage and spray tube out of the dye-vat.—P. F. C.

Dyeings with sulphide dyestuffs; Treatment of black —. R. vom Hove. Ger. Pat. 204,412, Oct. 9, 1907.

BLACK dyeings on cotton with sulphide dyestuffs may be rendered fast to rubbing and soaping by treating the goods, 12 hours after dyeing, with a hot solution of sodium sulphide.—T. F. B.

Reducing agents; Manufacture of new — and method of printing with their aid. A. Ashworth, Bury. Eng. Pat. 17,734, Aug. 24, 1908.

By acting upon zinc dust with sulphur dioxide in the presence of glycerin or glucose, suitably diluted with water or with a solution of zinc chloride or calcium chloride, a reducing agent is formed which is stable and reduces indigo at low temperatures. Example:—Into a well stirred mixture of 20 parts of zinc dust, 15 parts of glucose, and 20 parts of a solution containing about 45 per cent. of calcium chloride, 29 parts of sulphur dioxide are introduced till the zinc dust has disappeared. The temperature of the mixture is kept at 50–55° C. during the reaction. The product is a thick greyish paste which can be used directly for printing. For this purpose 40 parts of the product, 30 parts of dry British gum, 10 parts of water, and 10 parts of turpentine are mixed, heated to 40° C., cooled, and mixed with 5 parts of sodium bisulphite containing 24 per cent. of sulphur dioxide. This discharge is printed on the goods, which are then dried and passed through a steam ager, supplied with moist steam at a temperature of 102–103° C.—P. F. C.

Green, olive, and brown shades in dyeing and printing; Production of —. H. Schmid. Fr. Pat. 392,891, Aug. 1, 1908. Under Int. Conv., May 4, 1908.

A RANGE of shades can be produced upon the fibre by oxidising the salts of *m*-aminophenols with alkali chlorates and ferrocyanides as in the production of Aniline Black. After the oxidation the fabric is chromed and washed. The shades thus obtained become browner on soaping and yellower by passing them through an alkaline bath. The *m*-aminophenols may be replaced by *m*-aminoresols, or may be mixed with *o*- and *p*-aminophenols.—P. F. C.

Decoration of fabrics; Process for the —. M. Ratignier and H. Pervillae et Cie. Fr. Pat. 393,412, Oct. 25, 1907.

A CYLINDER engraved with a network or other desired design is arranged to rotate underneath a hopper which distributes on to the cylinder a plastic coating of collodion or other similar preparation. After passing this distributor, the surface of the cylinder is brought into contact with a doctor which removes the excess of the plastic preparation. The fabric, which is to be decorated, passes from one

roller to another and during its passage is made to press tightly on the engraved cylinder, which is adjusted so that its peripheral velocity is the same as the velocity with which the fabric travels. During the time of contact, the collodion contained in the engraving of the cylinder is transferred to the fabric. In the case of openwork fabrics it is necessary to provide a backing which can support the design and for this purpose the machine is so arranged that the fabric is pressed against the cylinder by a roller carrying an endless band on to which a layer of flocks has been distributed. Where the plastic preparation comes in contact with the fabric, the flocks adhere and provide a suitable backing to hold the design.—P. F. C.

Scouring of fabrics dyed or printed with vat dyestuffs. Badische Anilin und Soda Fabrik. Fr. Pat. 392,858, July 31, 1908. Under Int. Conv., Mar. 31, 1908.

FABRICS, after being woven, are often cleaned by boiling them with a dilute solution of sodium hydroxide, with or without pressure. This process is injurious to most dyestuffs and in the case of fabrics which have been dyed or printed with vat dyestuffs, the size present in the fabric occasionally reduces the dyestuff and a part of the latter thereupon dissolves in the sodium hydroxide solution and is re-dyed on to another part of the material. It is found that this difficulty can be avoided by adding a small quantity of some easily reducible organic compound to the scouring bath. The salts of the mono- or disulphonic acids of anthraquinone or of nitrobenzene are specially suitable for the purpose.—P. F. C.

Fabrics; Process for rendering certain — impermeable. J. R. Blum. Fr. Pat. 392,870, Oct. 8, 1907.

CELLULOSE is dissolved in acetone, ether, amyl acetate, or other solvent, and the article to be treated is dipped into the solution. On drying, the solvent evaporates, leaving the article completely covered with a thin pellicle of celluloid. This operation is repeated until a coating of the desired thickness has been obtained.—P. F. C.

Dyeing sulphur [sulphide] dyestuffs; Process of —. A. Wöschel, Assignor to Farbwerke vorm. Meister, Lucius, and Brüning, Höchst on Main, Germany. U.S. Pat. 907,937, Dec. 29, 1908.

SEE Eng. Pat. 8631 of 1907; this J., 1908, 559.—T. F. B.

Printing with sulphide dyestuffs with the aid of copper or brass rollers; Process for —. Soc. pour l'Industrie Chimique à Bâle. Fr. Pat. 393,893, Nov. 9, 1907.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Potassium chlorate; The purity of commercial —. G. Pöndorf. Chem.-Zeit., 1908, 32, 1151—1152. (See this J., 1908, 806, and 1909, 21.)

It was found by Gartenmeister (this J., 1907, 223) that solutions of certain samples of potassium chlorate give an immediate blue coloration when treated with starch, potassium iodide, and dilute sulphuric acid, and he assumed that this was, as a general rule, owing to the presence of chlorites or hypochlorites. The author, however, examined five samples of chlorate, all of which were free from chlorite and hypochlorite, and several of which had been prepared electrochemically. One grm. of each sample was dissolved in 25 c.c. of water, a small crystal of potassium iodide added, a few drops of starch solution and then 0.5 c.c. of dilute sulphuric acid (1:4). A blue coloration appeared after 2½ minutes with the first sample, and immediately with

the other samples. A portion of each was then mixed with some ammonium nitrate and powdered resin, and heated in an oil-bath. The first sample exploded at 127—132° C. Mixtures of other samples exploded at temperatures between 126° C. and 173° C. One sample, of German origin, did not cause an explosion of the mixture when heated to 170° C. It consequently does not follow that a sample of potassium chlorate, which gives an immediate coloration with the iodide test, will be more liable to cause premature explosion or ignition under the conditions named, or in a word, to be more dangerous than one which does not respond to the iodine test. Moreover, an electrochemically prepared chlorate has been used for many years in the Kriewald Powder Factory without any mishap.—F. SIDA.

Chlorates; The "active" substance in —. H. Klopstock. Chem.-Zeit., 1909, 33, 21. (See this J., 1907, 223.)

THE active substance (iodine reaction) in potassium chlorate made at the Aussig works was found to be, not chlorite at all, but potassium bromate. This was formed at the anode from bromide existing as an impurity in the potassium chloride used. Sodium chlorate produced electrolytically did not show any "activity," the sodium chloride used never being contaminated by bromide.—J. T. D.

Sulphur and sulphides; Spontaneous oxidation of —. E. Pollacci. Monit. Scient., 1908, 22, 373—375.

FINELY-DIVIDED sulphur when mixed with water and exposed to the air is oxidised to sulphuric acid, the process being accelerated by movement of the air and by exposure to sunlight. The oxidation is not caused by oxygen nor by neutral hydrogen peroxide, and is not due to decomposition of the water, since it does not take place in an atmosphere of hydrogen. It appears to be caused by the ozone present in the air; ozonised air acts more rapidly than ordinary air. Sulphides, especially when finely divided, are also oxidised by the air, even at temperatures below 30° C., but not directly to sulphates as is generally believed. The oxidation proceeds in two stages, just as with hydrogen sulphide: first sulphur is liberated and the oxide of the metal is formed; secondly, the sulphur is oxidised to sulphuric acid which unites with the oxide, giving the sulphate. There are considerable differences in the rates at which different sulphides are oxidised, but the change is sufficiently marked to be taken into consideration in analytical determinations in which metals or metalloids (bismuth, cadmium, mercury, arsenic) are weighed as sulphides. It is suggested that sulphur might be obtained in considerable quantities by passing natural waters containing hydrogen sulphide through beds of ochreous earth, allowing the iron sulphide formed to oxidise in the air, and recovering the liberated sulphur by distillation or treatment with carbon bisulphide.—A. S.

Graphite; Formation of — by the interaction of magnesium powder and carbonates. H. R. Ellis. Faraday Soc., Dec. 15, 1908. [Advance proof.]

When a mixture of magnesium powder and a carbonate is ignited at one point, interaction proceeds vigorously and a very high temperature is reached. In the author's experiments, in which the carbonates of cadmium, ammonium, magnesium, and the alkaline-earth metals were used, a mixture of graphite and amorphous carbon was found amongst the products. By burning 25 grms. of magnesium powder in a stream of dry carbon dioxide, about 2.5 grms. of carbon, containing 12 per cent. of graphite, were obtained, a very slight amount of carbide being also detected.—F. SODA.

Nitric acid; The electric discharge and the production of —. W. Cramp and B. Hoyle. See XI.A.

Zeolites and similar compounds, their constitution and technical importance for agriculture. R. Gans. See XV.

Sulphuric acid; Determination of — as barium sulphate. E. Ruppin. See XXIII.

Ammonia production of Great Britain in 1908. Bradbury and Hirsch, Liverpool. [T.R.]

THE total production of ammonia from all sources in the United Kingdom, calculated into ammonium sulphate, during 1908 was as follows:—

	1908.	1907.
	Tons.	Tons.
Gas works	161,000	165,000
Iron works	20,000	21,000
Shale works	51,000	51,000
Coke and carbonising works and producer gas.....	79,000	75,500
	314,000	313,000

Of this production England contributed 206,500 tons, Scotland 105,000 tons, and Ireland 2,500 tons. The stock brought forward from 1907 was 15,000, making the supply for 1908, 329,000 tons. The exports during 1908 were 235,000 tons and the home consumption was 83,000 tons, leaving stock to carry forward into 1909, 11,000 tons.

Sulphuric acid; Removal of sulphurous fumes and their recovery as —. H. Kühne. Fr. Pat. 393,461, Aug. 19, 1908. Under Int. Conv., Aug. 20, 1907.

THE sulphurous fumes mixed with air (or oxygen) and water (or steam or dilute sulphuric acid) are exposed to the action of a source of light rich in ultra-violet or similar rays, such as a mercury vapour lamp enclosed in a quartz globe, the sulphurous acid being thus converted into sulphuric acid. The latter may be either absorbed, condensed, or recovered in the form of metallic sulphates, and it is stated that the conversion is almost complete even when the proportion of sulphurous acid in the fumes is less than 1 per cent. Aqueous solutions of sulphurous acid mixed with air may be treated in the same manner.—C. J. G.

Vapours of volatile acids, especially nitric acid; Apparatus for the condensation and absorption of —. Scherfenberg und Prager. Ger. Pat. 202,500, Feb. 16, 1907.

A COOLING device formed of several upright condensing tubes, is arranged as a reflux condenser directly over the condensing tower. The pipe leading from the tower to the reflux condenser is provided with a rose, so that the ascending vapours are atomised and come into intimate contact with the descending condensed liquid.—A. S.

Alkali hydrosulphite; Preparation of — from zinc hydrosulphite or its double salts and complex compounds. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 203,910, Jan. 28, 1908.

ZINC hydrosulphite and its double salts, such as zinc-sodium hydrosulphite, and complex compounds such as the double compound of zinc hydrosulphite and ammonium chloride, are easily soluble in ammonia. On adding the requisite quantity of a sodium or potassium compound to a concentrated ammoniacal solution of this kind, the corresponding alkali hydrosulphite separates in a few hours as a crystalline mass.—A. S.

Alkali hydrosulphites; Preparation of —. Badische Anilin und Soda Fabrik. Ger. Pat. 201,063, Dec. 12, 1907. Addition to Ger. Pat. 119,676.

A MIXTURE of 145 grms. of caustic soda lye (containing 27.5 per cent. of sodium hydroxide) and 200 c.c. of water is prepared in a vessel from which air is excluded, 40 grms. of zinc dust are added, and then sulphur dioxide is led in until the mixture has gained 96 grms. in weight, the vessel being cooled and shaken during this operation. The

mixture is now allowed to stand for some hours, with frequent agitation, then milk of lime (40 grms. of quicklime and 120 c.c. of water) is added, and after again standing for several hours, with frequent agitation, the concentrated solution of sodium hydrosulphite is separated by suction.—A. S.

Sodium perborate; Preparation of — from sodium metaborate and hydrogen peroxide. C. von Girssewald. Ger. Pat. 201,279, July 20, 1907.

AN aqueous solution of 76.5 parts of borax and 21.6 parts of 90 per cent. sodium hydroxide is mixed with 950 parts of 3 per cent. hydrogen peroxide, and a concentrated solution of sodium chloride is then added until a permanent turbidity is produced, the temperature being kept below 10° C. On placing the mixture in an ice-chest, a yield of 87.5 per cent. of the theoretical quantity of white, nearly chemically pure sodium perborate crystallises out.—A. S.

Potassium sulphide lyes; Decomposition of — with carbonic acid. J. A. Reich. Ger. Pat. 204,526, March 8, 1907.

IS the usual process of decomposing potassium sulphide lyes by carbon dioxide at the ordinary temperature, or with the application of gentle heat, considerable time is required for the decomposition of the sulphide. According to the present patent, it is stated that solutions free from sulphide are quickly obtained if the liquor be strongly cooled during the passage of the carbon dioxide.—A. S.

Ozone; Fixing — in liquids. S. Fraser, London. Eng. Pat. 26,949, Dec. 6, 1907.

THE claim is for fixing ozone in solution by passing it into a liquid containing paraldehyde, $C_6H_{12}O_3$. Fatty, vegetable, mineral, or other substances, and also alcohol, may be added to the paraldehyde solution.—C. J. G.

Nitrogen; Process for preparing pure — from combustion gases. A. Frank and N. Caro. Ger. Pat. 201,882, May 22, 1907.

COMBUSTION gases, e.g., from a gas producer, containing carbon dioxide, carbon monoxide, hydrocarbons, oxygen, and nitrogen, are passed over a heated mixture of a metal and its oxide, e.g., copper and copper oxide; the metal is oxidised by the oxygen, whilst the carbon monoxide and hydrocarbons are oxidised to carbon dioxide by the metallic oxide. In this way a mixture containing only nitrogen and carbon dioxide is obtained, from which the latter is removed by absorption in the usual manner.

—A. S.

Sulphur; Process for obtaining — from metallic sulphides which are decomposed on heating. E. Fleischer. Ger. Pat. 205,017, April 21, 1907.

THE process consists in distilling off a portion of the sulphur from metallic sulphides, such as iron disulphide, and at the same time leading air and steam into the roasting furnace, whereby the residual sulphide is decomposed with formation of sulphur dioxide and hydrogen sulphide. The gases from the furnace, containing excess of steam, are cooled first to a temperature above 100° C. in order to condense the sulphur vapour, and are then further cooled, and if necessary, water added, in order to cause interaction of the sulphur dioxide and hydrogen sulphide with liberation of sulphur.—A. S.

Orygnitrogen compounds; Process for the transformation of hydrocyanic acid into —. O. Dieffenbach and W. Moldenhauer, Darmstadt, Germany. Eng. Pat. 8768, April 22, 1908. Under Int. Conv., April 24, 1907.

VIII.—GLASS, POTTERY, AND ENAMELS.

Plate-glass; Manufacture of —. H. Knoblauch. Sprechsaal, 1908, 41, 704–706, 719–721.

THERE are three kinds of plate-glass—the cast or moulded, the hand-worked or blown, and the so-called “shock” glass. Cast-glass, once outstripped by every other form of glass, has greatly improved and now holds its own. Plates may be cast up to 25 sq. m. in area. The metal is generally fired in a Siemens regenerative gas-furnace. In composition, it resembles window-glass, but is less fusible. It is made up of 100 parts of sand, 40–43 of sodium sulphate, and 40–45 of calcium carbonate. The pot of melted glass is swung by a crane over the moulds, and the plates of glass are run, as quickly as possible (in order to prevent curling at the edges), into the cooling-oven, which starts at a bright red-heat and cools down gradually. Owing to the uniformity of the cooling, cast-glass cuts easily and straightly. It is then ground between two tables revolving in opposite directions by sand of increasing fineness, and ultimately polished by iron oxide. The plates must be true and upright, and are used for show-windows, business plates, table-tops, and on tombs. While cast-glass is about 5 mm. thick, blown glass can be made from 8–1½ mm. thick. This property enables it to be put to many uses—for working with brass, for ornamental ware, and furniture. For these purposes it is often silvered to act as a mirror. It is made up of 100 parts of sand, 40 of sodium carbonate, and 25 of chalk. The melting is not so complete as with cast-glass. “Shock” glass is not thicker than a well-worked delicate window-glass, and can be conveniently considered in that branch. It is generally silvered for mirrors, and must be quite free from all flaws. It is also used for toy-making and for photographic plates.—H. H. S.

Vitreous enamelling metal or glass; Home Office Regulations for —. Statutory Rules and Orders, 1908, No. 1258, Dec. 18, 1908. [T.R.]

WHEREAS the process of vitreous enamelling of metal or glass has been certified in pursuance of section 79 of the Factory and Workshop Act, 1901, to be dangerous, the Home Secretary has made the following Regulations, and directs that they shall apply to all factories and workshops in which vitreous enamelling of metal or glass is carried on.

Provided that nothing in these Regulations shall apply to—

- (a) the enamelling of jewellery or watches; or
- (b) the manufacture of stained glass; or
- (c) enamelling by means of glazes or colours containing less than 1 per cent. of lead.

These Regulations shall come into force on 1st April, 1909.

Definitions.

In these Regulations—

“Enamelling” means crushing, grinding, sieving, dusting or laying on, brushing or woolling off, spraying, or any other process for the purpose of vitreous covering and decoration of metal or glass;

“Employed” means employed in enamelling;

“Surgeon” means the Certifying Factory Surgeon of the district or a duly qualified medical practitioner appointed by written certificate of the Chief Inspector of Factories, which appointment shall be subject to such conditions as may be specified in that certificate;

“Suspension” means suspension by written certificate in the Health Register, signed by the Surgeon, from employment in any enamelling process.

Duties.

It shall be the duty of the occupier to observe Part I. of these Regulations.

It shall be the duty of all persons employed to observe Part II. of these Regulations.

PART I.—DUTIES OF EMPLOYERS.

1. Every room in which any enamelling process is carried on—

(a) shall contain at least 500 cubic feet of air space for each person employed therein, and in computing this air space no height above 14 feet shall be taken into account;

(b) shall be efficiently lighted, and shall for this purpose have efficient means of lighting, both natural and artificial.

2. In every room in which any enamelling process is carried on—

(a) the floors shall be well and closely laid, and be maintained in good condition;

(b) the floors and benches shall be cleansed daily and kept free of collections of dust.

3. No enamelling process giving rise to dust or spray shall be done save either—

(a) under conditions which secure the absence of dust and spray; or

(b) with an efficient exhaust so arranged as to intercept the dust or spray and prevent it from diffusing into the air of the room.

4. Except in cases where glaze is applied to a heated metallic surface, dusting or laying on, and brushing or woolling off, shall not be done except over a grid with a receptacle beneath to intercept the dust falling through.

5. If firing is done in a room not specially set apart for the purpose, no person shall be employed in any other process within 20 feet from the furnace.

6. Such arrangements shall be made as shall effectually prevent gases generated in the muffle furnaces from entering the workrooms.

7. No child or young person under 16 years of age shall be employed in any enamelling process.

8. A Health Register, containing the names of all persons employed, shall be kept in a form approved by the Chief Inspector of Factories.

9. Every person employed shall be examined by the Surgeon once in every three months (or at such other intervals as may be prescribed in writing by the Chief Inspector of Factories) on a date of which due notice shall be given to all concerned.

10. The Surgeon shall have power of suspension as regards all persons employed, and no person after suspension shall be employed without written sanction from the Surgeon entered in the Health Register.

11. There shall be provided and maintained for the use of all persons employed—

(a) suitable overalls and head-coverings, which shall be collected at the end of every day's work, and be cleaned or renewed at least once every week;

(b) a suitable place, separate from the cloakroom and mealroom, for the storage of the overalls and head-coverings;

(c) a suitable cloakroom for clothing put off during working hours;

(d) a suitable mealroom separate from any room in which enamelling processes are carried on, unless the works are closed during meal hours.

12. There shall be provided and maintained in a cleanly state and in good repair, for the use of all persons employed, a lavatory, under cover, with a sufficient supply of clean towels, renewed daily, and of soap and nail brushes, and with either—

(a) a trough with a smooth impervious surface, fitted with a waste pipe with plug, and of such length as to allow at least two feet for every five such persons, and having a constant supply of warm water from taps or jets above the trough at intervals of not more than two feet; or

(b) at least one lavatory basin for every five such persons, fitted with a waste pipe, and placed in a trough having a waste pipe, and having either a constant supply of hot and cold water or warm water laid on, or (if a constant supply of heated water be not reasonably practicable) a constant supply of cold water laid on and a supply of hot water always at hand when required for use by persons employed.

13. The occupier shall allow any of H.M. Inspectors of Factories to take at any time sufficient samples for analysis of any enamelling material in use or mixed for use.

Provided that the occupier may at the time when the sample is taken, and on providing the necessary appliances, require the Inspector to take, seal and deliver to him a duplicate sample.

No results of any analysis shall be published without the consent of the occupier, except such as may be necessary to prove the presence of lead when there has been infraction of these Regulations.

PART II.—DUTIES OF PERSONS EMPLOYED.

14. Every person employed shall—

(a) present himself at the appointed time for examination by the Surgeon as provided in Regulation 9;

(b) wear the overall and head-covering provided under Regulation 11 (a), and deposit them and clothing put off during working hours, in the places provided under Regulation 11 (b) and (c);

(c) carefully clean the hands before partaking of any food or leaving the premises;

(d) so arrange the hair that it shall be effectually protected from dust by the head-covering.

15. No person employed shall—

(a) after suspension, work in any enamelling process without written sanction from the Surgeon entered in the Health Register;

(b) introduce, keep, prepare, or partake of any food, drink, or tobacco, in any room in which an enamelling process is carried on;

(c) interfere in any way, without the concurrence of the occupier or manager, with the means and appliances provided for the removal of dust or fumes, and for the carrying out of these Regulations.

PATENTS.

Glass: Apparatus for the manufacture of sheets of —. F. L. O. Wadsworth, Assignor to Pressed Prism Plate Glass Co. Morgantown, W. Va. U.S. Pat. 907,656, Dec. 22, 1908.

A SHEET of glass is first formed by passing glass between two rollers. This sheet then passes between a third roller and a table. In the surface of this third roller grooves are formed, which correspond with grooves formed in the table, so that the sheet of glass produced is of unequal thickness.—A. G. L.

Granite: Recovering china clay from decomposed, and china stone from partly decomposed —, and separating the clay from mica and quartz, and the mica from the quartz; applicable also to treating ochre and the like. A. E. Gaved, St. Austell, Cornwall. Eng. Pat. 6794, Mar. 27, 1908.

DECOMPOSED or partly decomposed granite is dried and broken up in a crusher from which it falls into a disintegrator, consisting of a tube in which a shaft provided with blades rotates, and in which it is further broken up. The coarse material falls out of the bottom of this tube, and may be re-treated, whilst the finer materials are carried by means of a current of air through aspirators, in which the materials are forced to pursue a zig-zag course, into grading chambers and finally into a dust-collector. The aspirators are provided with flap-doors, which open from time to time under the weight of the sand which settles on them, whilst the mica and china-clay pass to the grading chambers, in which the mica settles first, the china-clay depositing further on. Grading is assisted by perforated baffle-plates inserted in the grading chambers. A spray of water may be injected into the further end of the chambers to cause the fine china-clay to settle. The materials from the grading chambers may be still further purified by treatment on oscillating sieves of the kind described in Eng. Pat. 27,034 of 1906 (this J., 1907, 1281).—A. G. L.

Kaolin, clay, and ceramic masses prepared therefrom: Process for rendering — plastic. G. Keppeler and A. Spangenberg. Ger. Pat. 201,404, Aug. 29, 1906.

THE process consists in adding tannic acid (or other complex organic acids such as humic acid), combined with alkali or ammonia to the clay or clay mass; or in first imparting to the mass a certain degree of mobility by addition of tannic acid and an excess of alkali, and then partially or completely destroying this mobility by addition of acid. It is stated that the mixtures when dried and burnt at temperatures below 600° C. yield light (sp. gr. 0.5) porous articles.—A. S.

Opaque enamels: Preparation of — by means of cerium compounds. Rickmann and Rappe, G.m.b.H. Ger. Pat. 203,773, June 30, 1907.

IT has been proposed to use the fluoride or silicofluoride of cerium for the production of opaque enamels, but during the melting process the effect of these compounds is partially destroyed; indeed on prolonged heating, the enamel mass dissolves them with production of a clear glaze. According to the present patent, this defect is overcome by replacing the compounds mentioned by cerium oxide or such cerium compounds, e.g., the carbonate, which yield the oxide, or by a mixture of oxides of cerium metals, such as is obtained as a by-product in the manufacture of thorium nitrate.—A. S.

Silvering glass or other surfaces. Chem. Fabr. von Heyden A.-G., Radebeul, Germany. Eng. Pat. 14,841, July 13, 1908. Under Int. Conv., July 18, 1907.

SEE FR. Pat. 392,243 of 1908; this J., 1908, 1204.—T. F. B.

Earthenware cocks and pipes. Eng. Pat. 15,189. See I.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Clays: Action of electrolytes on the colloidal substances of —. Rohland. Sprechsaal, 1909, 42, 1—3.

ALL electrolytes, which on dissociation give rise to hydrogen ions, increase the plasticity of clays, i.e., render them stiffer, if the concentration of the electrolytes is not less than that of a $N/10$ -hydrochloric acid solution.

Conversely, electrolytes, which yield hydroxyl ions, render clays thinner, and thus make them more suitable for pouring, if the concentration is not less than that of a $N/1$ -sodium hydroxide solution. The explanation of these facts is assumed to be that the colloids, hydroxides of iron, aluminium, and silicon, formed by the action of water on clays, possess a negative charge, and are attracted by, and form complex compounds with, the positively charged hydrogen ions, whilst they are repelled by hydroxyl ions. In cases, *e.g.*, with copper sulphate, ammonia, and potash alum, where a concentrated solution has an action the reverse of that shown by a dilute solution of the same electrolyte, it is assumed that the anion acts in the dilute solution, and the cation in the concentrated solution. Clays possess the peculiar property of adsorbing carbonic acid ions completely from solutions of alkali carbonates; phosphoric acid ions are also partially adsorbed. Talc (magnesium silicates) possess the same property, but to a less extent. Hydroxyl ions act most strongly on dark-coloured clays, which contain organic matter, and it has been proposed to render clays more fluid by adding, in addition to alkalis, organic colloids, such as peat and lignite. In selecting clays for casting, the nature of the soluble salts contained in the clays should not be overlooked, since all neutral salts are not so inert as is sodium chloride; magnesium and iron salts, sulphates and carbonates especially exert specific actions.—A. G. L.

Molasses binder [roads]. Rock Products, 8, Sept. 26. Chem. Abstr. (Amer. Chem. Soc.), 1908, 2, 3414. [T.R.]

THE public roads department of the U.S. Department of Agriculture has experimented at Newton, Mass., with molasses as a road binder. The molasses used was the lowest grade from the cane sugar refineries of the Southern and the beet sugar factories of the Western and Northern States. It was nearly as black and thick as tar, and almost as powerful as a binder. Having always been a waste product, it can be bought at a lower price than coal tar and in greater quantities. Samples of this molasses were subjected to laboratory tests. The molasses was blended with oils and lime water, mixed with rock dust, with earth and with sand and subjected to the action of heat and water. It behaved so well and held out such promises for ideal roads that a practical test was decided upon.

X.—METALS AND METALLURGY.

Iron ores of Ontario. A. B. Willmott. J. Canadian Min. Inst., 1908, 11, 106—124.

IN 1907, the production of iron ore in Ontario was 200,185 tons, the total mined from 1869 to 1907 being little more than two million tons. The author passes in review the principal areas in Ontario in which iron ores are found, but points out that the prospecting in these regions has been comparatively superficial. More than half of the ore mined is hæmatite, but magnetite, limonite, chalybite, and titaniferous iron ores are also found. As the geological formation in which the vast high-grade Lake Superior iron deposit is situated extends into Ontario, the author considers that similar deposits may be expected there. Up to 1907, over 330 million tons of ore had been produced

from the Lake Superior deposits and it is estimated that on the basis of last year's consumption, they will not last more than fifty years. In discussion, F. Hill maintained that the Mattawin Iron Range was the most important iron deposit in the province, for though the ore was of low grade, it was readily concentrated to a high-grade Bessemer ore with hardly any phosphorus or sulphur. This deposit was known to cover an enormous area and drilling to a depth of 1000 ft. had failed to reach the bottom.—F. R.

Charcoal: the blast furnace fuel for Ontario. R. H. Sweetzer. J. Canadian Min. Inst., 1907, 11, 163—169.

THE fuel cost in Ontario is high on account of the necessity of importing coal or coke, but as there is an abundance of wood, the use of charcoal is advocated. The author claims that the destruction of forests would not seriously affect the province for many years. Charcoal forms a very efficient fuel for the smelting of iron ores, owing to its freedom from sulphur, and, in consequence of its low percentage of ash, both the amount of fuel and flux may be materially reduced. The air blast required is only 65 per cent. of that necessary for a coke furnace, with the result that, in addition to the saving in blowing engines, etc., the quantity of fine dust is reduced, and yield of pig iron increased. The furnaces for the use of charcoal are however comparatively small, and size for size, their output is less, compared with coke. Complete data are given of a furnace running one month on coke and one month on charcoal.—F. R.

Tin; Determination of — in tin-plate. K. Meyer. Z. angew. Chem., 1909, 22, 68—69.

THE method gives concordant results and occupies only 20 minutes. 20—50 grms. of cuttings or small pieces of the tin-plate, freed from dirt and grease, are covered with water, heated to 80 °C., and 1—2½ grms. of sodium peroxide added. After the first vigorous reaction has subsided, another 1 gm. of peroxide is added, the heating being continued so that the solution boils. When reaction has ceased, the residual metal is examined, and if necessary, a further small quantity of sodium peroxide is added and the mixture boiled to dissolve the last traces of tin. The metal is then washed with water, and with alcohol, dried and weighed. If desirable, the tin in the solution may also be determined. Any lead present is dissolved with the tin.—A. S.

Lead and tin alloys; The coefficient of viscous traction of —. A. E. Dunstan. Phil. Mag., 1909, 17, 192—201.

IT is shown that when a wire composed of pure lead, or tin, or alloys of these metals, is stretched beyond its elastic limit, (in these cases this limit is exceeded by a very small load), the rate of extension proceeds quite steadily, and the material undergoes a "viscous flow." From this rate of flow a coefficient of viscous traction may be deduced for any given load. It is further shown that on plotting the corresponding coefficients of viscous traction against the percentage composition of the alloys, a hyperbolic curve is obtained, which indicates that the relative effect of tin on the mobility of lead is very great, whilst that of lead on the mobility of tin, is very small. The maximum divergence from the normal, did these alloys follow the mixture law, is at 2Pb:1Sn. The coefficient of viscous traction is a function of the load, and in some cases is very considerably affected by the load used. This statement is, however, strictly applicable only to those alloys containing less than 10 per cent. of tin.

[Alloys] *Hardness of solid solutions and compounds of metals.* N. Kurnakow and S. Shemtschukhy. J. Russ. Phys.-Chem. Ges., 1908, 40, 1067—1104. Chem. Zentr., 1908, 2, 1990—1992.

FROM a study of the hardness of metallic alloys it is found that the formation of a solid solution is accompanied

by an increase of hardness. The curves representing the hardness of binary alloys may be divided into four main types. (1). When the metals form a continuous series of mixed crystals, the hardness is represented by a continuous curve passing through a maximum; the point of maximum hardness generally corresponds with that of minimum electric conductivity. (2). When the alloys solidify as a mechanical mixture of the two components, the hardness is represented by a straight line; in most cases, however, this form of curve is modified owing to deformation of the crystals of the individual metals. (3). When the two metals form only a limited series of mixed crystals, the curve is a combination of those described under (1) and (2). (4). If the two metals form a definite chemical compound, this may be harder or softer than the component metals, and the curve representing the hardness of the alloys differs accordingly.

—A. S.

Monel Metal. Eng. and Min. J., Dec. 26, 1908. [T.R.]

ATTENTION has been called to this alloy recently by its use in the sheet form in the roof of the new Pennsylvania railroad station in New York. It is laid in the same manner as copper sheets would be, and the sheets are fastened with nails made of the same alloy.

Monel metal is an alloy containing about 70 per cent. of nickel and 30 per cent. of copper. It is smelted and refined directly from nickel-copper matte produced from ores of the Sudbury district in Canada. The furnacing and refining of the matte involves only the removal of impurities and the reduction of the iron which is contained in the matte to a very small proportion, 1.5 per cent. being the maximum. Monel metal has a high tensile strength, the tests showing much higher results than those given by nickel steel. Its hardness makes it more difficult to roll than steel sheets. A special mill will probably be required. The new alloy resists corrosion, takes a fine polish, and possesses many of the qualities of metallic nickel. Perforated sheets for mining screens have been tried, and have been found to wear better than any other metal yet used for the purpose. Notwithstanding the high nickel content, the metal is placed on the market at about 2c. per lb. above the current price of copper. This can be done because the process of separating the nickel from the copper is not required; the alloy, as above stated, being made directly from the nickel-copper matte.

Aluminium, calcium, and magnesium; Heats of combustion of —. F. E. Weston and H. R. Ellis. Faraday Soc., Dec. 15, 1908. [Advance proof.]

THE authors have investigated the reduction of the oxides of aluminium, calcium, and magnesium by each of these metals respectively. Aluminium oxide is reduced by magnesium and by calcium; calcium oxide is easily reduced by magnesium and partially reduced by aluminium; magnesium oxide is slowly reduced by calcium, but not by aluminium. The conclusion is drawn that the heat of combustion of magnesium is slightly greater than that of calcium, and that the latter is greater than the heat of combustion of aluminium.—F. SODDY.

Carborundum [Production of metallic silicides]. L. Baraduc-Muller. Soc. Ing. Civ. de France, Proc. verb., 1908, 245—247.

AFTER a description of the history of the production of carborundum and a résumé of its properties and applications, the author describes the reaction, at temperatures about 1350° C. of carborundum on metallic oxides, expressed by the general equation, $\text{SiC} + \text{MO} = \text{MSi} + \text{CO}$. In this way it is possible to prepare many metallic silicides practically free from carbon. By carrying out this reaction on the surface of a bath of melted steel (or even pig-iron), special ternary or quaternary steels can be produced at a single operation.—J. T. D.

Thorium. C. Baskerville. Eng. and Min. J., 1908, 86, 1241—1242.

THORIUM, though of rare occurrence, is of wide utility in consequence of its use in the manufacture of the

Welsbach incandescence mantle. The chief minerals in which thorium occurs are thorite, aegirite, thorianite, and monazite, most of the commercial thorium being obtained from monazite. It is also found in a greater or less quantity in many other rare minerals, the author giving a statement of the composition of 80 minerals in which it is said to occur, together with a description of the mineralogical qualities and reactions of the most important.—F. R.

Mercury in 1908. Chem. and Druggist, Jan. 15, 1909. [T.R.]

Bessemer process; Basic —. L. P. J. A. H. Messier, Lille, France. Eng. Pat. 8168, Apr. 13, 1908.

IN treating pig-iron poor in phosphorus or high in silicon, a portion of the basic slag obtained in a previous operation is added from a slag-mixer to the metal after it has been sufficiently freed from silicon. Lime is then added and the basic process completed as usual. If a cupola furnace is used for melting the pig-iron, the slag may be added in the cupola furnace instead of in the converter.—A. G. L.

Carburising gas [for case-hardening iron and steel]; Preparation of —. A. W. Machlet, Elizabeth, New Jersey, U.S.A. Eng. Pat. 10,532 of 1908; date of application, Nov. 12, 1907.

IN the process of case-hardening iron and steel by means of illuminating gas, as described in Eng. Pat. 25,087 of 1907 (see Fr. Pat. 389,547; this J., 1908, 985), the gas should be diluted with an inert gas. The invention consists in producing a suitable diluted carburising gas by passing an inert gas, such as ammonia, through a body of naphtha.—A. T. L.

Steel; Process of manufacturing —. W. R. Walker, Chicago, Ill. U.S. Pat. 906,757, Dec. 15, 1908.

THE spiegel to be added to the charge of a Bessemer converter, or steel-refining chamber, is made by tapping a spiegel, low in manganese, into a receiving ladle and mixing with it sufficient of a metallic addition rich in manganese, to produce the necessary recarburising material.—F. R.

Ore separators; Centrifugal —. P. F. Peek, Chicago, U.S.A. Eng. Pat. 3683, Feb. 18, 1908.

THE specification relates to modifications of the ore separator described in Eng. Pat. 3682 of 1908 (this J., 1908, 1209). Owing to the strong flow of water over the different zones of the separating channel, there is a tendency for part of the water to flow over, carrying ore particles with it, from one zone to the next adjacent ones. In order to overcome this difficulty, water-partition or bulkhead zones, supplied independently with clean water, are provided between the concentrates-removing zones and the ore-receiving and separating zones.—A. S.

Ores, shale, or other substances; Apparatus for subjecting — to the action of heat in a continuous manner. J. B. Peat, Redcar, Yorks. Eng. Pat. 7920, Apr. 9, 1908.

SOLID or gaseous fuel is burnt in grates or burners placed in a brick combustion chamber in such a way that the flames are forced to take a spiral path through the chamber before entering a central chimney through an opening arranged for the purpose. In doing so, the flames heat a number of separate and easily removable tubes, which extend vertically through the chamber, and through which the material to be heated falls on its way from a chamber above the combustion chamber to another chamber placed below it. From the lower chamber the burnt materials are removed by a conveyor or other device without admitting air. To the upper chamber the unburnt materials are charged from a hopper placed above, also without admitting air. The central brick chimney of the combustion chamber is continued upwards through the upper chamber and the hopper by means of a suspended metal shaft, made tight with asbestos packing, thus allowing for expansion and contraction. In the upper chamber the materials are heated centrally from this chimney after being preheated in the hopper; in the tubes the material is heated from outside. The tubes are provided with internal spiral retarders or ribs, which serve to turn the materials over in their downward passage; the tubes may also be provided with external baffle-plates to take up heat more readily from the flames.

—A. G. L.

Ores; Process of desulphurising —. R. Hübner, New York. U.S. Pat. 906,883, Dec. 15, 1908.

THE ore is placed in an externally heated chamber and the evolved gases withdrawn by suction, the chamber being otherwise closed to prevent the entrance of any material amount of air.—F. R.

Metals; Process of uniting —. E. D. Holley, Forestville, and C. L. Root, Bristol, Conn. Assignors to Bristol Brass Co., Conn. U.S. Pat. 906,627, Dec. 15, 1908.

Two metals are united by coating the surface of one of them with an adherent metallic medium, fusible at a lower temperature than either, and then applying the second metal in a molten condition and allowing it to cool naturally. Iron and copper are united by applying a coat of molten zinc to the surface of the iron and then pouring on the molten copper.—F. R.

Ore concentrating and separating apparatus. F. and H. Dallemagne, Passages, Spain. Eng. Pat. 11,684, May 29, 1908. Under Int. Conv., June 15, 1907.

SEE Fr. Pat. 378,895 of 1907; this J., 1907, 1203.—T. F. B.

Zinc; Apparatus for extracting —. E. H. Shortman, Bloxwich, Assignor to The New Delaville Spelter Co., Ltd., Birmingham. U.S. Pat. 907,416, Dec. 22, 1908.

SEE Eng. Pat. 7223 of 1907; this J., 1908, 450.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Nitric acid; The electric discharge and the production of —. W. Cramp and B. Hloye. Paper read before the Institution of Elect. Eng., Nov. 3, 1908.

THE authors discuss the various types of apparatus which have been proposed for the electrical oxidation of atmospheric nitrogen. They conclude that good results are only to be obtained by the use of thin flames with very rapidly moving arc-threads employed to heat suddenly large quantities of air which are as quickly as possible

cooled again. On this basis experiments were made, with a modification of the apparatus suggested by Werner (See U.S. Pats. 777,987—777,991; this J., 1905, 95), in order to ascertain the effect of variations in: (1), the size and form of the nozzle through which the air is delivered; (2), the electric current; (3), the velocity of the air; (4), the length of the spark-gap; (5), the capacity of the circuit. The results show broadly the great importance of adapting spark-gap, current, and air-blast to one another, for changes of yield to the extent of 50 per cent. or more may be obtained by slight variations of any one of these factors. For a given current the maximum yield of acid does not correspond with the maximum concentration of acid, and the value of using a magnetic field to spread out the flame, as in the Birkeland-Eyde process, is hence doubtful. If in the Birkeland-Eyde process, as at present carried on, a very good proportion of the maximum possible yield is being obtained, then direct electrical processes would appear to possess no chance of competing effectively with the calcium cyanamide process of Frank and Caro. Further experiments are needed to ascertain whether much better yields of oxides of nitrogen can be obtained by making use of the most favourable velocity of air and length of spark-gap, the introduction of ozone, the instantaneous cooling of the gaseous products, and subjecting these products to ionisation. A bibliography is appended to the paper. (See also Guye, this J., 1906, 567, and Howles, this J., 1907, 290.)—A. S.

Electrolytic bleaching process; Preparation of alkali hypochlorites, and the —. F. J. G. Beltzer. See V.

PATENTS.

Hydrogen and oxygen generators; Electric —. S. O. Cowper-Coles, London. Eng. Pat. 14,285, Dec. 20, 1907.

THE electrodes consist of metallic sheets provided with tongues, which project downwards at an angle of about 45° with the faces of the sheets. The electrodes are placed in separate collecting boxes or chambers, the liberated gases being guided into these by the inclined tongues of metal which project within openings in the sides of the chambers. A battery of generators may be enclosed in a water jacket, and provided with means for keeping the solution in each cell at a common level.—B. N.

Electrode for use in the purification of water and other liquids. J. M. Murphy, Hammonton, N.J., U.S.A. Eng. Pat. 27,559, Dec. 13, 1907.

THE electrode is composed of from 87 to 93 parts of aluminium and from 7 to 13 parts by weight of magnesium; the alloy is melted, cast into a plate, and the surface of the latter is polished. When in use, two plates are fixed in suitable proximity, and the liquid to be purified is passed between them, while a current of electricity (of about 30 volts and 20 ampères) is passed through the electrodes and liquid.—W. P. S.

Ozone; Apparatus for the production of —. J. Steynis, New York, and H. J. E. Chaumat, Paris. Eng. Pat. 412, Jan. 7, 1908. Under Int. Conv., Jan. 25, 1907.

THE air or oxygen ozonised in this apparatus is previously cooled by adiabatic expansion with external work. The electrodes form two alternated systems of conducting plates, connected in parallel, the electrodes of one polarity being fixed and the others forming a whole which may be displaced in the direction of the movement of the air, so that the amount of the silent discharges may be varied. The insulating blocks which separate the dielectric plates also serve to support the electrodes. The insulating blocks have grooves in which the electrodes are fixed in such a manner that the insulating blocks are outside the zone of the silent discharge.—O. F. H.

Electrical resistances; Manufacture of —. C. Ruzicka, London. Eng. Pat. 4657, Mar. 2, 1908.

THE resistances are made from a mixture of substances, such as coal tar or rosin, which leave behind a carbon-

aceous residue when heated in a neutral or reducing atmosphere, or a vacuum, and mineral substances such as quartz and silicon borate. To this mixture are added one or more metallic salts to act as fluxing or welding agents, the whole being heated to a temperature of at least 1000° C. so as to yield a hard stone-like homogeneous product. For a resistance rod of 1 sq. cm. cross section and 10 cm. long, having a resistance of 10,000 ohms, the following composition is specified—coal tar, 60 parts; quartz, 12; potassium feldspar, 21; and potassium tetraborate, 10 parts. For a resistance rod of the same dimensions to give a resistance of 20,000 ohms, the following composition is specified—rosin, 60 parts; flint, 12; potassium feldspar, 24; boric acid, 10; and turpentine, 30 parts.—O. F. H.

Electrical resistances; Manufacture of —. C. Ruzicka, London. Eng. Pat. 9762, May 5, 1908.

THE resistances are made of a mixture of either an oxide, carbonate, chloride, nitrate, or nitrite of at least one metal of each of the following two groups—(a), copper, iron, and silver; (b), iridium, nickel, palladium, and platinum; together with one or more artificial or natural compounds of silicic or boric acid or both, these compounds possessing a comparatively low melting temperature of less than 1500° C. To this mixture are added one or more natural or artificial minerals having a comparatively high melting temperature of over 1500° C., such as bauxite or alumina. For a resistance rod of 1 sq. cm. cross section, 10 cm. long, and having a resistance of 300 ohms, the following mixture is given—iron oxide, 20 parts; nickel oxide, 33; calcium feldspar, 26; and bauxite, 18 parts. For a resistance rod of similar dimensions having a resistance of 2 ohms, the following mixture is given—iron nitrite, 20 parts; nickel nitrite, 38; calcium feldspar, 26; and bauxite, 18 parts.—O. F. H.

Electrical resistances; Manufacture of —. C. Ruzicka, London. Eng. Pat. 9763, May 5, 1908.

CLAIM is made for the use of metallic salts as fluxing or welding agents in the manufacture of electrical resistances. For a resistance rod of 1 sq. cm. cross section and 10 cm. long, having a resistance of 400 ohms, the following mixture is given: carbonised petroleum residue, 4 parts; potassium feldspar, 34; quartz, 22; coal tar, 4; and boric acid, 6 parts. For a resistance rod of the same dimensions and having a resistance of 60 ohms, the following mixture is given: silicon carbide, 60 parts; potassium feldspar, 24; marble, 12; tar pitch, 3; boric acid, 10; and amyl alcohol, 10 parts.—O. F. H.

[Electrolytic] Precipitating apparatus. J. E. Greenawalt, Denver, Colo. U.S. Pat. 906,011, Dec. 8, 1908.

THE precipitating vessel has a perforated false bottom on which a mass of shavings cut from an alloy of lead and zinc and forming the cathode is supported. A suitable anode contained in a porous jar is suspended just below the surface of the liquid or electrolyte. The liquid to be treated is introduced by a pipe which enters the side of the vessel below the false bottom, passes upwards through the metallic shavings, and overflows through a pipe near the top of the vessel.—W. H. C.

Electrolytic apparatus for the manufacture of bleaching liquors. A. Vogelsang, Dresden, Germany. U.S. Pat. 906,669, Dec. 15, 1908.

THE apparatus consists of a series of compartments, arranged in steps, in which chloride solutions are electrolysed. The walls between the compartments serve as electrodes and the liquid flows through the compartments in succession. The sides of the division walls between the compartments, which are exposed to the air, do not act electrolytically and have tubes arranged near them for cooling the flowing liquor.—J. W. H.

Electric furnace. K. Birkeland, Christiania, Norway. U.S. Pat. 906,682, Dec. 15, 1908.

A TUBULAR electric furnace for the treatment of gases has axial electrodes arranged at a distance apart greater

than that at which the arc may be re-formed. The furnace is surrounded by a field coil, producing a magnetic field parallel to the axis of the electrodes, by which the arc is distorted into a helical form. The air or gas for treatment is admitted at one end of the furnace and exhausted from the other.—J. W. H.

Chlorates and perchlorates; Process and apparatus for the electrolytic preparation of alkali —. F. Silbermann. Ger. Pat. 205,019, Nov. 7, 1907.

IN the electrolytic preparation of chlorates and perchlorates, the electrolyte soon becomes alkaline, and the excess of free alkali has a prejudicial effect on the yield. In order to overcome this defect, a method of working is adopted in which the electrolyte flows continuously through the apparatus at a suitable rate and rinses the surface of the cathode just before leaving the electrolytic vessel. In this way small quantities of free alkali are continuously removed from the system, before they can interact with chlorine formed at the anode. For this purpose, the cathodes are enclosed in open tubes through which the electrolyte flows to the discharge tube, or they are themselves made hollow in order to serve as outlet tubes for the electrolyte.—A. S.

Oxidising agents, such as hypochlorites, chlorates, bromates, etc.; Electrolytic production of —. G. Thiele. Ger. Pat. 205,087, July 11, 1906.

IN the electrolytic preparation of oxidising agents, such as hypochlorites, chlorates, etc., without the use of a diaphragm, it has been proposed to add calcium or chromium compounds to the electrolyte, in order that the oxide or hydroxide of the added metal may form a protecting layer on the cathode, and prevent cathodic reduction of the oxidising agents formed. According to the present patent, high-molecular, non-aromatic, organic sulphur compounds, such as Turkey-red oil or other sulphonated or sulphurised fats or fatty-acids, or soluble soaps prepared from them, are added, along with calcium compounds, such as the chloride or hydroxide, to the electrolyte either before or during electrolysis. It is stated that the organic sulphur compounds increase the protective action of the calcium hydroxide.—A. S.

Persulphates; Process for the preparation of — by electrolysis of bisulphates. Verein. Chem. Werke, A.-G. Ger. Pats. 205,067 and 205,068, April 14, 1907.

INCREASED yields of persulphate are obtained by the addition to the electrolyte of: (1), simple or complex cyanides; (2), salts of cyanic acid, thiocyanic acid, or cyanamide.—A. S.

Sodium persulphate; Process for the preparation of — by electrolysis of sodium bisulphate. Verein. Chem. Werke, A.-G. Ger. Pat. 205,069, June 14, 1907.

IN order to obtain sodium persulphate in a granular form, so that it can be readily separated from the mother-liquor, small quantities of potassium salts, especially salts of cyanogen-compounds, are added to the electrolyte.—A. S.

Electrolytic cells. A. E. Gibbs, Wyandotte, Mich., U.S.A. Eng. Pat. 27,830, Dec. 17, 1907.

(B.)—ELECTRO-METALLURGY.

PATENTS.

Iron: Electro-deposition of —. S. O. Cowper-Coles, London. Eng. Pat. 12,747, Dec. 2, 1907.

FINELY-DIVIDED iron in the form of cast-iron chilled shot is maintained in suspension in the electrolyte by the following or other suitable means: The electrolyte and shot are withdrawn from the bottom of the depositing vat into a vat at a lower level. The electrolyte passes into a sump from which it is pumped back to the depositing vat, while the shot is elevated by a series of perforated buckets attached to an endless chain and tipped into a hopper on the top of the depositing vat, and thence into the electrolyte. The object of the finely-divided iron is to keep the electrolyte neutral.—O. F. H.

Electrodeposition. L. Hausmann, Berlin. Eng. Pat. 25,669, Nov. 20, 1907. Under Int. Conv., Nov. 23, 1906.

AN anode with metallic surface containing a metal core is used in connection with the process described in Eng. Pat. 14,904 of 1907 (this J., 1908, 232).—O. F. H.

Scrap tin or the like: Receptacles for — for electrolysis. The London Electron Works Co., Ltd., and A. de Back, London. Eng. Pat. 17,115, Aug. 14, 1908.

THE sides, ends, bottom and top, of the receptacle containing the scrap tin to be detinned electrolytically, are made of perforated metallic flat plates, connected together so as to form a perforated vehicle or cage, preferably of rectangular form. One side of the cage is made easily removable for the introduction of the material. The ends project above the top level of the cage, and are connected to a non-insulated electric conductor, or crossbar, the latter being provided with electrical contact studs or bolts, and with a hook for attachment to lifting gear. The studs are connected to a source of current, so that the cage forms the anode.—B. N.

Detinning tin scrap: Apparatus for and method of —. M. Leitch, Springfield, Mass., Assignor to Metal Process Co., New York. U.S. Pats. 906,726 and 907,061, Dec. 15, 1908.

THE apparatus consists of cathode and anode plates, specially arranged in a tank containing an electrolyte such as caustic soda. The tank or the electrodes can be raised or lowered, for the immersion or otherwise of the latter. Pipes are provided for withdrawing the electrolyte at a point below its surface, passing it through a tank where it is heated, and returning it to the detinning tank.—F. R.

Furnaces: Electric —. C. A. Keller, Paris. Eng. Pat. 21,741, Oct. 14, 1908.

THE base or sole of the furnace comprises a bundle of vertical iron bars embedded or countersunk into a setting of suitable fireproof material, such as magnesite, the upper ends of the bars being flush with the upper surface of the material, whilst the lower ends are electrically connected with a horizontal conducting plate. The bars of metal conduct the current when cold, but at higher temperatures

the refractory earth also becomes a partial conductor. "The semi-metal and semi-fireproof block," thus forming the lower electrode, is contained in a surrounding metal frame, which may be water-cooled, and the electrode and metal casing are separated by a refractory brick lining.—B. N.

Silicides of barium, calcium, and strontium: Preparation of — in the electric furnace. T. Goldschmidt, Ger. Pat. 204,567, May 19, 1907.

THE oxide or salts of calcium, barium, or strontium are heated with silicon, in the presence of a flux capable of yielding a friable slag. When calcium chloride is used as raw material, calcium fluoride is a suitable flux. For instance, 15 parts of calcium fluoride, 5–10 parts of calcium chloride, 66½ parts of lime, and 33½ parts of silicon are heated in the electric furnace, and from the product the light grains of the silicide are separated from the friable slag by sifting.—A. S.

Alloys of silicon [silicides]: Manufacture of —. Th. Goldschmidt, Essen on Ruhr, Germany. Eng. Pat. 5773, March 12, 1908. Under Int. Conv., May 18, 1907.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Red currant seed oil. R. Krzizan, Chem. Rev. Fett- u. Harz-Ind., 1909, 16, 1–3.

THE air-dried seeds of Italian and Bohemian red currants yielded, on extraction with petroleum spirit, 16.0 and 18.5 per cent. of oil respectively. In each case the oil was of an orange-yellow colour and had an odour resembling that of linseed oil. In the film test the oils dried in 3 to 4 days, yielding an elastic skin, and in Livache's test absorbed 9.24 and 8.78 per cent. of oxygen respectively in 7 days. The oil from the Italian seeds had a high acid value (40.6) possibly due to the presence of a lipolytic enzyme; its sp. gr. was 0.9265 at 15° C., saponification value, 189.9; iodine value, 172.3; Reichert-Meißl value, 1.1. The Bohemian oil, extracted from freshly-separated seeds only showed an acid value of 2.9, but when kept in closed vessels became light yellow, and strongly rancid. It had the sp. gr. 0.9303 at 15° C., saponification value, 186.9; iodine value, 175.9. The Italian oil contained 0.14 per cent. of sulphur, but none was found in the Bohemian oil. The 5 per cent. of solid fatty acids separated from the Italian oil had the sp. gr. 0.9117 at 15° C., iodine value, 178.7; neutralisation value, 196.3; acetyl value, 13.2. They contained stearic and palmitic acids, whilst the liquid fatty acids consisted chiefly of linolic acid with smaller quantities of oleic, linolenic, and (probably) isolinolenic acids. The tetrahydroxystearic acid obtained by the oxidation of the linolic acid melted at 157° to 158° C. instead of the normal m. pt. (173–174° C.), and in this respect resembled the tetrahydroxystearic acid obtained from blackberry seed oil (this J., 1908, 233). The Bohemian oil contained less solid fatty acids than the Italian oil. (See also this J., 1908, 1072).—C. A. M.

Salvadora oleoides fat [khakas oil]. D. Hooper, Agricult. Ledger, 1908, [1], 1–5.

KHAKAS oil is obtained by hot expression from the kernels of the seeds of *Salvadora oleoides*, indigenous to the Punjab, Baluchistan, Sind, and Bombay, where it often forms the greater part of the desert vegetation. The fat occurs in yellowish-white blocks, solid at ordinary Indian temperatures; the odour is slightly rancid. Sp. gr., 0.9084; m. pt., 41° C.; acid value, 11.26; saponification value, 242.36; iodine value, 7.48; Reichert-Meißl value, 1.28; fatty acids, 94.12 per cent.; titer test, 40° C.; acid value of fatty acids, 244.42; iodine value of fatty acids, 8.3. The fat can be easily saponified. It should be useful for candle making, for hard soaps, or for pharmaceutical products. It is used by native Indian dyers as a "resist." Its low iodine value and high saponification

value distinguish it from other Indian fats, such as Malabar tallow, from *Vateria indica*, and kokum butter from *Garcinia indica*. J. O. B.

Oils; Iodine value of —, L. E. Levi and E. V. Mameel. J. Amer. Leather Chem. Assoc., 1908, 3, 386—387.

EXPERIMENTS with cod, olive, sperm, neatfoot, and "tan" oils showed that carbon tetrachloride or pentachloroethane may be substituted for chloroform in the determination of the iodine value of oils by the Hanus method. Carbon tetrachloride is preferred, it being easily obtainable at a comparatively low price. Two methods are given for its purification. (1). Commercial carbon tetrachloride is shaken with a solution of sodium thiosulphate at intervals of half an hour for two hours. The two layers are then separated, and the carbon tetrachloride next shaken with a 5 per cent. solution of caustic soda every 15 minutes for one hour. It is again separated, dried over calcium chloride, and distilled. (2). In the other method of purification the Hanus iodine solution is used instead of the sodium thiosulphate solution. H. G. B.

Unsaturated organic compounds [fats, fatty acids, etc.]; Catalytic oxidation and reduction of —, S. Fokm. J. Russ. Phys.-Chem. Ges., 1908, 40, 276—321. Chem. Zentr., 1908, 2, 1995—1996.

The author has continued his studies on the catalytic oxidation of unsaturated organic compounds (see this J., 1907, 1149). In the oxidation of olein, tung oil, sunflower oil, almond oil, and the fatty acids of linseed oil, using as catalysers ("driers") the oleates of cobalt, manganese, chromium, nickel, barium, lead, and calcium, the compounds of cobalt and manganese gave the best results, whilst those of lead and calcium were the least active. There appears to be no simple relation between the rate of oxidation and the concentration of the catalyser. The rate of oxidation is retarded by moisture, increased by light, doubled by a rise of temperature of 10° C., and greatly accelerated by increasing the pressure of the oxygen from 1 up to about 20 atmospheres.

Further experiments on catalytic reduction are also described (see this J., 1906, 935; 1907, 169, 1149; 1908, 878).—A. S.

Colloidal solutions of calcium soaps in heavy mineral oils. Holde. Z. Chem. Ind. Kolloide, 1908, 3, 270—274.

CERTAIN lubricating greases (known as Stanffer's or Toyote greases) are usually prepared by dissolving a calcium soap in a mineral oil and thoroughly stirring in a little water. Less frequently a saponifiable oil is dissolved in a mineral oil, the solution treated with lime and so much water left in the product that on stirring, the peculiar consistence of these lubricants, resembling that of vaseline or tallow, is obtained. When not mixed with water they are not stable, and the constituents separate out. The water is present in the form of microscopic drops, and when present in the proper quantity, increases the consistence of the product very greatly and raises the dropping point very considerably, in some cases converting a product which is quite liquid at the ordinary temperature into one with a dropping point of 70° C. The point of greatest consistence is characterised by a peculiar cracking noise which is produced on stirring. The turbidity of the mixture is in close relation to the amount of water. The magnitude of the difference between the softening and dropping points (in Ubbelohde's apparatus) is considered to be of great technical importance. It becomes large, if too much oil is used, or if the oil is too thin, or if the conditions under which heat is applied during preparation are unsuitable. On standing, the lubricant becomes more consistent and the softening point gradually rises, though the dropping point remains unaltered. This phenomenon is in the author's opinion connected with the fact that solutions of calcium soaps in mineral oil, to which water has not been added, gradually become non-homogeneous, the calcium soap separating out locally in the form of a jelly. In the finished product the increased viscosity due to the finely-divided water prevents this change from being outwardly noticeable; the product may probably be looked upon as a supercooled colloidal

solution of the calcium soap. Very different results are obtained on preparing the calcium soap by precipitation of an alkali soap with calcium chloride. Under the ultramicroscope, solutions of calcium soaps in heavy mineral oil appear homogeneous, but solutions of precipitated calcium soaps in pure benzene show submicrons. Crystallised paraffin wax shows a light-cone, but few submicrons, except in very strong solutions; in Russian petroleum which is almost free from paraffin wax, scarcely any submicrons could be observed, but they were present in an American petroleum, containing paraffin wax. —E. F.

Sewage, waste-water, etc.; Apparatus for the extraction of grease from —. Fr. Pat. 393,172. See XVIII B.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A).—PIGMENTS, PAINTS.

PATENTS.

White lead pigment; Process for the preparation of —, J. M. Neil, Assignor to J. B. Gregory, Toronto. U.S. Pat. 906,454, Dec. 8, 1908.

A SOLUTION of lead chloride is treated with a sulphate, and the precipitated lead sulphate is washed thoroughly and mixed with a half-molecular proportion of lead chloride. The mixture, having the composition, $2\text{PbSO}_4 + \text{PbCl}_2$, is then treated with a boiling solution of an alkali hydroxide, until the lead chloride is converted into hydroxide. The resulting precipitate, after washing and drying, has the composition, $2\text{PbSO}_4 + \text{Pb(OH)}_2$.—E. W. L.

White pigment with lead sulphate as basis; Manufacture of —, L. S. Hughes. Fr. Pat. 392,990, Aug. 6, 1908.

ORES or other compounds containing lead sulphide are crushed so as to pass a sieve of 24 meshes per cm. The crushed material is fed into the bottom of a vertical sheet-iron furnace where it is projected upwards, by a blast of air, through a zone of oxidising flame. This flame is produced by burning gas with excess of air, the mixture being introduced into the furnace through the jets of a ring burner. The metal walls are protected by the introduction of an upward current of cold air through apertures near the bottom of the furnace. The object of making the furnace entirely of metal, without a fire-resisting lining, is in order to prevent, as far as possible, the superheating of the burning ore, which would result in the fusion of some portions of it, and in the oxidation of the iron sulphide present, thus rendering the sulphate of lead (principally basic sulphate, $\text{Pb}_2\text{S}_2\text{O}_5$) impure. The blast of air, and the fan used to draw off the products of combustion, are regulated so that the unoxidised particles of ore are not carried over. The separation of the pigment from impurities, and from the gases, is effected by gravitation and filtration.—E. W. L.

Paint and varnish; Antirouling —, M. Ulrich, Assignor to Farbenfabrik, vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 906,668, Dec. 15, 1908.

THE varnish or paint consists of dinitro-ortho-cresol associated with suitable solvents.—J. W. H.

(B.)—RESINS, VARNISHES.

PATENT.

Resinous products similar to natural resins: Manufacture of —. Les Prod. chim. de Croissy, Ltd. Fr. Pat. 392,978, Oct. 12, 1907.

A VOLATILE liquid such as benzol, benzine, alcohol, ether, carbon tetrachloride, etc., is used as a means of moderating the heat developed in the preparation of resinous products by the action of phenols upon aldehydes in presence of catalytic agents. The vapours of the volatile solvent—which is added to the other ingredients before the reaction begins—may be condensed, and the liquid be either allowed to flow back into the reaction vessel, or recovered for future use. A form of apparatus is described, the condensing-worm of which can be utilised for either purpose, by the manipulation of cocks.—E. W. L.

(C.)—INDIA-RUBBER, &c.

Cryptostegia grandiflora in South-East Madagascar. H. Jumelle. Caout. et Gutta-Percha, 1908, 5, 2410.

THE analyses summarised in the following table represent the composition of samples of *Cryptostegia grandiflora* rubber from various sources, viz.:—(1). Sample from Madras, flat cake, dark brown outside, light in colour and porous inside, some of the pores containing uncoagulated latex and a brown acid liquid. Soft, but not tacky, elastic and showing good "nerve." Became hard and diminished in strength after some time. (2). Sample from Jalau, irregular leaves, black inside and out, very porous, and containing much bark. Physically greatly inferior to sample (1). (3). Sample from Bombay, lump apparently made up of scraps. Deeply coloured, of medium strength, and containing much impurity. (4). Sample from South-East Madagascar, which the author regards as the native habitat of the lina. Prepared by heating the diluted latex. Brownish-black in colour. Retained its elasticity, "nerve," tensile strength, and freedom from tackiness after two years. When rolled out into thin sheet was of a light colour. (5). This represents a sample of *C. madagascariensis* rubber for comparison. The relatively low resin content of sample (4) should be noted.

India-rubber Market, 1908; S. Figgis and Co.'s Annual Review of the —. [T.R.]

Plantation rubber in Ceylon and British Malaya.—The acreage under rubber plantation (partly mixed with other products) is now nearly 500,000 acres.

	1908.	1907.	1906.	1905.
Exported from—	tons.	tons.	tons.	tons.
Ceylon (& India)	350	230	160	70
Malaya, &c. ..	1,450	780	350	75
Tons ..	1,800	1,010	510	145

There has been a further general improvement in preparation, less of inferior and "tacky," much more of fine clean crêpe—some of very good colour realising high prices—

and nice resilient sheet. The variations and advance in prices since early October have resulted in very high "average price" for Plantation during recent months, but, the difference in value compared with fine Para Brazil rubber, lessens with the larger supply of Plantation. Manufacturers have shown a decided preference for sheet, biscuit and crêpe; the latter should not be drawn out too thin or have visible air or steam bubbles in it, some lots of strong thick crêpe sold very well. It has been profitable to planters to wash and clean the rubber thoroughly, and to prepare as large a proportion as possible of good colour—also not to send many qualities or very small lots. Block has not been in favour generally, and unless clean resilient hard quality can be sent, it may be better to ship as crêpe or sheet. It should be packed in good dry condition (excess of resin is much disliked) in strong cases of 1 cwt. to 2 cwt. each. No paper, fullers earth, &c., is to be used.

Different qualities and colours and, where practicable, immature rubber should be kept separate; it is best to send separately dirty barked pieces, and to wash out all the bark in crêpe, block, and sheet. All fine qualities should be loose crêpe, sheet, or biscuit—not run to a mass.

Smoked rubber appears to have greater resiliency and to be more suitable for many purposes than unsmoked. "Smoking" prevents the "proteins" in rubber from decomposition, and generally from "tackiness." All fine rubber from Para is smoked.

India Rubber of all Kinds.

The world's supply in 1908 was about 65,000 tons, against 69,000 tons in 1907, and 65,000 tons in 1906. Consumption was about 67,500 tons.

Of rubber planted there is in the East nearly 500,000 acres—

	1908.	1907.	1906.
	acres.	acres.	acres.
Ceylon	180,000	150,000	100,000
Malaya, Malacca, etc. (containing about 20 million trees, not two million tapped in 1908)	185,000	100,000	90,000
Borneo and New Guinea	10,000	9,000	8,000
Dutch East Indies (60,000 Java, 30,000 Sumatra), &c.	90,000	70,000	25,000
India and Burma	30,000	—	—

Mexico, Nicaragua, and Honduras have plantations but are not increasing—probably by now 20,000 acres planted; also Colombia, Ecuador, Bolivia, and Peru.

India is extending, probably about 30,000 acres planted. Some in Burmah and Mergui: the Philippines (small as yet), Samoa, Hawaii, and beginning in New Guinea and other Islands, Queensland and Seychelles. The West Coast of Africa has plantations, and more progress has been made in the Congo region and German West Africa, also in British East Africa, Uganda, and the West Indies probably 2,000 acres.

Brazil exported in 1908 about 40,000 tons against 41,500 tons in 1907, Manicoba seriously decreased, also Guayule from Mexico, largely used in America and the Continent. Prices of Guayule are very much lower and quality improved; probably 2,000 tons were made.

PATENTS.

Rubber goods; Use of naphthalene and its derivatives in the manufacture of —. Rütgerswerke-Akt. Fr. Pat. 393,186, Aug. 10, 1908.

THE claims are for the use of naphthalene and its derivatives, and of analogous substances, in the manufacture of rubber goods: (1), in place of and in the same manner as vegetable waxes, paraffin wax, ceresin, fats and oils, which are employed in rubber mixings in order to assist the mixing process, and to minimise micro-porosity; (2), in place of the same substances in the treatment of waste rubber in order to bring the latter into a condition in which it can be readily worked up again; (3), in place of benzine, benzol, and similar solvents for spreading purposes. In case (1) only small additions of naphthalene, from about 0.5 to 5.0 per cent., are necessary as a rule; only in extreme cases is an addition of as much as 10 per cent. required. In case (2) 10 per cent. may be regarded as an average proportion of naphthalene. In preparing "doughs" for spreading, either on the spreading-machine, or on the calenders (case 3), the proportion of naphthalene should vary considerably according to the kind of rubber used. Mixings containing balata or guayaquil require, for example, about 25 per cent., whereas a Ceara mixing, heavily loaded, will often require about 80 to 100 per cent. of naphthalene. Fabrics which have been spread with such "doughs" still retain some 3 to 6 per cent. of naphthalene after being kept for some time.—E. W. L.

Ebonite; Manufacture of a substitute for hard vulcanised rubber or —. E. Torrini, M. Hoffmann, and A. Benoit, Courbevoie, France. Eng. Pat. 10,731, Aug. 1, 1908.

HORN or other gelatinous material is powdered, treated with an alkaline solution, dried, treated with a solution of bichromated albumin or gelatin, again dried, moulded under pressure, and then exposed to light so as to render the gelatin insoluble.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tanning materials; Extraction of —. W. Eitner, Gerber, 1908, 34, 291—293, 305—307, 319—320, 333—334.

THE author points out that the tannin estimated by analysis is not always of practical use in the tannery, and that even with that part of the estimated tannin which is useful, there is a different value for each chemical individual according to its characteristic effect. The effect of increased temperature of extraction is discussed and it is emphasised that although this may bring a greater proportion of the material into solution, it involves also the development, formation, and solution of dark colouring matters and has also a deleterious effect on the easily decomposable tannins. It is the tannins which are soluble with difficulty which are readily decomposed, and which need the high temperature to bring them into solution; it is such tannins, also, which in practice are of little or no use. It is therefore not desirable to push the extraction too far, either by the employment of heat or of extraction in closed vessels under pressure. It is also necessary to consider whether fresh material or "fishings" from the dusters and layers is to be extracted. In the latter case the proportion of ineffective tannins is much greater,

partly because of the free acids which cause a decrease in the solubility of the less soluble tannins and partly because the material has already been leached to some extent, the easily soluble tannins having dissolved in the liquors in which the dusting material was used. Even in fresh material, however, the proportion of useful and useless tannin is not constant, but is variable for the same tanning material as well as for different tanning materials, being largely dependent on whether the tanning material is liable to form the less soluble varieties. The greater this tendency the greater the differences observed between the proportions of the two classes of tannin. These views are borne out by experimental work with the following materials. *Pine bark* with a mean tannin content of 13.5 per cent. was (1), leached for the early stages of sole leather tanning in an open battery of 8 vessels, the last three of which were heated. The spent tan had a mean tannin content of 2.62 per cent., consisting entirely of ineffective tannin insoluble at ordinary temperatures. The same bark (2), similarly leached, except that hot water was poured on to the "tail leach" and no further heating given, gave a mean result of 5.8 per cent. of tannin in its spent tan, which also consisted entirely of useless tannin. Another bark (3), extracted in an open battery of 7 vessels to yield handler liquors, showed 4.06 per cent. of residual tannin after leaching, all of which was soluble with difficulty. Another bark (4), containing only 12 per cent. of tannin, was leached in an open battery of 8 vessels, employing heat, and gave a spent tan with 4.39 per cent. of residual tannin in it. As the most rational process is that by which all the effective tannins are obtained at the minimum of cost and trouble, example (2) is clearly the most efficient. A sample of old bark (5), extracted as in example (4), gave a residue of 6.8 per cent., but this consisted of strongly coloured as well as difficultly soluble substances, illustrating therefore that the quality of the material influences the extent of leaching. *Pine bark "fishings"* (6), containing about 9 per cent. of tannin were leached as in example (3), but with 6 vessels, and yielded a residue of 5.54 per cent. consisting entirely of difficultly soluble tannins. The author concludes that pine bark contains about 5 per cent. of useless tannin, the proportion being greater in old bark and less in young bark. *Oak bark* (containing about 11 per cent. of tannin) was leached by various methods in different factories and yielded the following mean residues of tannin, 2.35, 2.74, 1.67, 2.13, 2.42, and 2.45 per cent. The author concludes, therefore, that the amount of difficultly soluble tannins is small and fairly constant, but that the more easily soluble part is just as easily extracted as that of pine bark. *Quebracho wood* contains about 20 per cent. of not very soluble tannin and is often extracted with heat and under pressure. The author states that about half the total tannin (10 per cent.) is fairly easily extracted, that 8 per cent. is a red tannin soluble above 40° C., and the remaining 2 per cent. is partly soluble in hot water and partly a source of dark resinous bodies. The proportion of these constituents varies considerably with the quality of the wood, and determines whether heat should be used in the extraction. The author obtained the following amounts of residual tannin after extraction:—

Extraction in open vessels.			Extraction in closed vessels under pressure.		
Example 1.	Example 2.	Example 3.	Example 4.	Example 5.	Example 6.
3.35	3.67	3.21	1.56	0.86	1.85
3.52	3.23	3.05	1.36	0.93	2.15
3.73	3.72	3.41	1.73	1.12	2.21
—	3.85	3.11	1.62	1.21	1.56
—	3.72	3.14	1.61	0.80	1.78
—	4.02	—	—	—	—
Mean 3.50	3.70	3.20	1.57	0.90	1.91

The residual tannin of those extracted under pressure contained only resinous bodies, but those extracted in open vessels contained in addition about 1.5 per cent. of the red tannin which is soluble above 40° C. In both cases therefore, the useful tannins are equally well extracted,

Myrobalans may be extracted whole or crushed, and yielded the following results:—

Extraction	Material	Tannin in spent tan.
under pressure	whole fruit	Per cent. 3.54
	crushed fruit	3.66
in open vessels	whole fruit	12.24
	crushed fruit	7.34, 6.72, 8.21, 7.66

The whole fruit is therefore generally employed for extraction under pressure and the crushed fruit for extraction in open vessels. The author considers that a myrobalans spent tan containing 7.5 per cent. of tannin will not yield much more effective tannin. *Mallet bark* yields very similar results, even in tanneries widely separated and with different methods of extraction. A spent tan from West Germany contained 9.42 per cent. of tannin, one from North Germany 9.80 per cent., from North Austria 9.60 per cent., and from Hungary 9.82 per cent. Hence it is concluded that mallet bark has a fairly constant proportion of easily and of difficultly soluble tannins, and that there is a sharp difference between their respective solubilities. The author assumes the presence of 9½ per cent. of ineffective tannin of the same nature as that in other materials. *Knopperrn* and *valonia* are used only as dusting material and are not leached separately, so that there is little evidence upon which to base conclusions, but some experiments with finely ground and specially extracted "fishings" indicate that these materials have about 5.2 and 7.2 per cent. of ineffective tannin respectively. *Divi-divi*, *algarobilla*, and *mimosa* bark have as yet supplied no data. The author also examined the behaviour of mixtures of tanning materials, with the following results, all mixtures being extracted in open vessels by a similar process:—

Mixture.	Tannin residues in spent tan, %	Mean of all experiments.	Calculated mean.
(1) 75 parts pine bark, 25 quebracho.....	4.13, 4.80, 5.19, 4.75, 4.41, 5.22	4.76	4.99
(2) 80 pine bark, 20 oak bark	4.25, 4.72, 4.33, 4.15	4.36	4.90
(3) 60 pine bark, 40 mangrove	8.15, 7.87, 7.76	7.93	7.30
(4) 70 pine bark, 30 mimosa	4.60, 5.01, 4.36, 5.13	4.90	5.05
(5) 50 pine bark, 50 myrobalans	5.91, 5.72	5.80	6.50
(6) 60 pine, 20 quebracho, 10 myrobs., 10 valonia	7.34, 7.87, 7.78, 7.80	7.70	6.70
(7) 60 pine, 20 mangrove, 20 myrobs.	7.23, 6.87, 7.52, 7.10	7.13	6.80
(8) 60 quebracho, 25 mangrove, 15 myrobs.	7.87, 7.32, 8.15, 8.69	7.75	5.72
(9) 60 mallet, 40 myrobs.	8.34, 8.83, 8.82	8.66	9.00

The difference between the experimental and calculated means is not great, and where distinct is readily explained by the insufficient data for the calculation. The author hence concludes that each material behaves the same in mixture as it does when used alone. Further discussion and experiments indicate also that extraction in open vessels is the most efficient and economical.—H. G. B.

Tanning materials; The colour valuation of —. H. C. Reed, J. Amer. Leather Chem. Assoc., 1908, 3, 382—385.

THE author criticises the methods at present in use for the estimation of the colour value of tanning materials, and suggests a new method of determination. The "pelt test," by which a small piece of prepared pelt is considered actually tanned with the material under examination, is useless, owing to the impossibility of obtaining pelt which will yield uniform and consistent results. The skins of the sheep, calf, and cow give varying colour valuations of the same tanning material, and portions of pelt even from the same skin produce irreconcilable results, whatever care is taken in their previous preparation. The "tintometer test," which indicates the relative proportions of red, yellow, and black in a solution of the tanning material, leaves it open to doubt whether these colours are fixed on the leather in the same proportions, and the author considers it not yet proved that there is a sufficient agreement possible between different analysts when this method is used. The author therefore experimented with the first type of method, but with material other than pelt. Cotton

cloth, wool cloth, and a good grade of white broadcloth were employed. Solutions of various tanning extracts were made, of 25 barkometer strength, and the cloth, after thorough wetting, was allowed to steep in the liquors for a definite period. The cloth was then squeezed from the liquor, washed thoroughly with water at the ordinary temperature, and permitted to dry after spreading on a glass plate while still wet. The colour valuations with broadcloth appear to be the most satisfactory, giving uniform and tangible results, and allowing a discrimination between extracts produced from the same crude material. —H. G. B.

"Galalith": A sensitive reaction for —. L. Wolter. Chem.-Zeit., 1909, 33, 11.

"GALALITH" is artificial horn prepared by the action of formaldehyde on casein. Skim milk is treated with caustic alkali or alkali carbonate, the casein is precipitated by addition of acid, pressed, impregnated with formaldehyde, and dried. This product has recently been used for the preparation of imitation tortoise-shell, and it is difficult to detect the imitation from the real material, until it has been in use for a short time. The author has found that treatment with fuming nitric acid affords a ready means of distinguishing "galalith" from tortoise-shell. A cutting of the material is boiled with a few c.c. of fuming nitric acid: "galalith" yields a heavy yellow crystalline powder, insoluble in water and the ordinary organic solvents, whilst tortoise-shell dissolves almost completely with the exception of fine, transparent scales; on adding water to the solution, amorphous flocks slowly separate. —A. S.

PATENTS.

Dressing leather; Process for — with oil by means of a torsion press. W. Marquardt. Fr. Pat. 392,188, July 9, 1908.

THE process consists in the preparation of leather from fresh skins by applying a mixture of tallow and fish oil to

the warmed skins and subjecting them to torsion in a special press. This consists of two beams capable of turning round the axis of an upright and of sliding up and down over this upright. The supports are bound to one another by free bolts disposed in a circle about the upright, between which the rolled up skins are placed and fastened by one extremity in a perforation of the axis of the upright. The skins are continually rolled up round this axis by the rotation of the beams and so tightened and squeezed. For complete conversion into leather it is necessary that the skins should be three times impregnated with fat and compressed in this way.—H. G. B.

Tanning skins; Process for —. C. W. Nance. Fr. Pat. 391,720, June 26, 1908.

THE process aims at making the tannage of skins more efficient by eliminating the oxygen from the tanning liquors before they come in contact with the skins. Tan liquors exposed to oxygen are said to be more prone to gallic fermentation, and to possess less penetrating power than liquors which have been deoxygenated. With this process, therefore, the circulation of the tanning liquor is effected by means of an aspirator, and not by means of pumps. A series of vats are arranged, which receive the skins to be treated, each one being provided with a deoxygenation chamber, and communicating by pipes with the cisterns containing the tan liquor, which are also provided with deoxygenation chambers, and connected by a pipe to the aspiration apparatus. The vats and cisterns are provided with air-tight lids which can be removed or brought into

position by cranks which cause them to slide over rollers. The vats are also fitted with horizontal celluloid stands on which the skins are laid; this ensures that the tan liquors will come in contact with every skin, and avoids also a needless excess of liquor. The skins are treated with deoxidised tan liquors of different strength, the last phase of tannage involving the use of more concentrated tan liquor and of powdered tanning bark, which last is disposed between the stands separating the skins. The skins are submitted to aspiration before admitting the tan liquor. When the tannage is complete, the excess of liquor is removed and the leather may be dried in the apparatus with the assistance of the aspirator.—H. G. B.

Leather, artificial; Manufacture of ——. A. Woonnam, London. From Oesterreichische Privivsin Akt.-Ges., Vienna. Eng. Pat. 4536, Feb. 28, 1908.

FINELY divided or powdered natural leather is distributed over the surface of a foundation of paper, fabric, felt, or the like, which has been coated previously with a suitable adhesive material. When the latter has dried, the layer of leather is subjected to a polishing, scraping, or grinding operation; for this purpose the coated surface may be drawn over rotating emery rollers. The ends of the fibrous coating material are thus removed and a smooth uniform surface is produced. Instead of leather powder, hide powder may be used and the tanning effected after it has been applied to the foundation.—W. P. S.

XV.—MANURES, &c.

Zeolites and similar compounds, their constitution and technical importance for agriculture. R. Gans. *Jahr. K. Preuss. Geol. Landesanst. u. Bergakad.*, Berlin. **26**, 179—211; **27**, 63—94. *Chem. Abs.* (Amer. Chem. Soc.), 1908, **2**, 3216—3217.

THE material soluble in dilute hydrochloric acid, obtained from soils, contains silicates which resemble zeolites, especially chabazite. Zeolites may be divided into two classes:—(1), those which readily exchange their bases on treatment with saline solutions, and (2), those in which the exchange proceeds only slowly. In those of the first class (aluminate-silicate zeolites), the bases are united only to the aluminium, the silicic acid being combined with such groups as $\text{Al}(\text{OH})(\text{ONa})$ or $\text{Al}(\text{ONa})$. In those of the second class (alumina-double-silicate zeolites), on the other hand, the bases are united directly to silicic acid. The zeolitic compounds of arable field soils belong to the aluminate-silicate group. The importance of these compounds in agriculture is discussed. The manufacture of artificial zeolites and their application to the purification of water and of sugar juice and molasses, have been described in this J., 1907, 215, 711, 1251; see also Ger. Pat. 174,097, and Eng. Pat. 8232 of 1907 (this J., 1907, 771, 1091). By passing a solution of a salt through different aluminates-silicates, different salts of the same acid may be prepared by the exchange of bases between the dissolved salt and the aluminate-silicate.—A. S.

Phosphate rock; Analysis of ——. C. F. Hagedorn, C. H. Denipwolf, jun., and F. B. Carpenter. *J. Ind. and Eng. Chem.*, 1909, **1**, 41—44.

THE paper comprises the report of a committee appointed by the National Fertiliser Association (U.S.A.) to examine the various analytical methods for phosphate rock. Four different kinds of phosphate rock were tested, the moisture, phosphoric acid, and oxides of iron and aluminium being determined. The phosphoric acid was determined by the official (U.S.A.) gravimetric method as magnesium-ammonium phosphate, Pemberton's volumetric method (this J., 1894, 176, 667; 1895, 511), the citrate method, and Gladding's method of weighing as ammonium phosphomolybdate. The oxides of iron and aluminium were determined by a modification of Von Guerber's method (this J., 1897, 164), Gladding's method (see J. Amer. Chem. Soc., **13**, 721), the acetate method, Glaser's method (this J., 1890, 111), Jones' method (this J., 1891, 387), and Wyatt's method of precipitating iron and aluminium

phosphates by acetic acid from a slightly ammoniacal solution. Pemberton's method and Gladding's method gave the most concordant results for phosphoric acid, but the committee considers there are not sufficient reasons for substituting either of these for the present official method, and they recommend the latter for referee work. For the determination of the oxides of iron and aluminium, the mineral should be dissolved in hydrochloric acid (1:1), and it is considered that a satisfactory modification of the acetate method would be useful as a standard on account of its simplicity. The work is to be continued in this direction.—A. S.

Superphosphate sacks. *Chem. Trade J.*, Jan. 9, 1909. [T.R.]

GREAT loss is incurred by the loss of superphosphate owing to the destruction of the bags by the free acid in the manure and repeated re-bagging, and the use of double bags to guard against this loss has become a heavy tax upon the farmer. In the annual report of the mines department of Western Australia the results are published of experiments made by the Government analyst during the year to see if a method could be devised to avoid this waste, and bags treated in various ways were submitted to practical test. One bag, which had been treated with a strong solution of red gum kino gave very satisfactory results. It was filled with a very acid superphosphate (which had completely rotted the double bags in which it had been imported) and was stored for six months surrounded and covered by other bags containing the same manure. At the end of six months, the bags by which it was surrounded had rotted and given way in all directions, but the bag treated with kino came out as strong and intact as when it was put into the store. This test was so satisfactory that many of those interested in the superphosphate trade are applying the method of treatment on a large scale, and there is every reason to hope that this simple and inexpensive method of preserving the bags will be effective.

PATENT.

Citrate-soluble phosphate; Preparation of a ——. H. Schroeder. *Ger. Pat.* 203,758, Jan. 17, 1908.

THE crude calcium phosphate is treated by one of the usual methods with a reagent capable of yielding calcium chloride, and then calcium oxide is added in sufficient quantity to convert the calcium chloride into oxychloride ($\text{CaO} \cdot \text{CaCl}_2$). The mixture of calcium oxychloride and citrate-soluble phosphate is a dry non-hygroscopic powder.—A. S.

XVI.—SUGAR, STARCH, GUM, &c.

Cane sugar juice; Relation between added water per cent. on cane and dilution per cent. on normal ——. F. N. Coombes. *Internat. Sugar J.*, 1909, **11**, 11—14.

N. DEER has pointed out that the amount of water used per 100 parts of cane for maceration after dry crushing, will always show a figure considerably greater than that expressing dilution per cent. on normal juice if the admixture of the added water has been complete. The author has found, however, that under laboratory conditions, 100 parts of a megass containing 45 per cent. of fibre, require about 200 parts of water for complete saturation; this corresponds to about 53 per cent. of water on canes containing 12 per cent. of fibre, and more water would be required under practical conditions. It must be remembered too, that the density of the juice expressed, decreases with each dry crushing, the density of the residual juice in the megass being less than that of the expressed juice from the cane. Taking the density of the expressed juice to be 18.2° Brix, and that of the residual juice in the megass to be 17° Brix, the author has shown that if instead of 53, only 26.5 per cent. of water is used for maceration (a more probable amount), then, assuming that half the layer of megass can be saturated thereby, and that it is crushed to 50 per cent. fibre after this maceration, the dilution per cent. on normal juice will

be 27·8, i.e., greater than the maceration water per cent. on cane. Under practical conditions, the dilution would probably be still greater. Similarly, if 13·25 per cent. of water is used for maceration and it is assumed that a quarter of the layer of megass can be saturated, the dilution will be 14·39 per cent. Should the maceration water per cent. of cane ever be higher than the dilution per cent. of juice, the cause might be found in a defective last mill crushing.—L. E.

Sugar in saturation mud; Determination of —. F. Herles. Z. Zuckerind. Böhm., 1909, 33, 254—264. (See also this J., 1908, 1033.)

SOME exception has been taken to the author's method of determining sugar in saturation mud (*loc. cit.*) on the grounds that it involves danger of formation of lead sucrate, that with excess of basic lead acetate, non-sugar may pass into solution, and that (according to Herzfeld) some saturation muds may contain more lime than that allowed for (*ibid.*). The author shows, however, that provided the aqueous sugar solution only contains lead in the form of basic acetate or of basic and normal acetate, no sugar is precipitated in the form of sucrate. He also points out that the amount of non-sugar in saturation mud, soluble in excess of basic lead acetate, is extremely small. As to Herzfeld's objection, the author observes that in the experiments on which this objection was based, the prescribed method was not adhered to, in that insufficient lead acetate was used, and that in some cases, amounts of lime were added to the mud far in excess of those found in practice. As regards some sucrose determinations in calcium sucrate, quoted by Herzfeld, the author points out that his method is not intended for the analysis of such material, though it could be modified to serve this purpose. One hundred c.c. of 20 per cent. solution of lead acetate suffice for 30 grms. of saturation mud containing not more than 4·9 per cent. of lime; if the percentage of lime is greater, the polarisation will be low, but such a condition is easily detected, since the filtrate will be alkaline to phenolphthalein. Should such a case occur, which the author doubts very much, a stronger solution of lead acetate (e.g., 30 per cent., sufficing for an alkalinity of 7·3 per cent.) could be used. Addition of ammonium nitrate and basic lead acetate to saturation mud causes error, since the ammonia set free precipitates lead hydroxide which combines with the sugar; use of ammonium nitrate alone may lead to practical difficulties. The author has also investigated the action of other salts in decomposing the calcium sucrate and fixing the free lime in saturation mud; for this purpose, magnesium chloride, nitrate, or acetate, or aluminium nitrate may be used (zinc nitrate and acetate, and magnesium sulphate are not so satisfactory) together with sufficient lead acetate or nitrate to form a basic salt. Basic lead acetate should not be used in conjunction with magnesium or zinc salts, but may be used together with aluminium nitrate (and probably with other aluminium salts also).

Molasses binder [for roads]. See IX.

Zeolites and similar compounds, their constitution and technical importance for agriculture. R. Gans. See XV.

PATENTS.

Sugar, etc.; Apparatus for boiling —. G. S. Baker. Fr. Pat. 392,948, Aug. 4, 1908. Under Int. Conv., June 1, 1908.

THE patent relates to apparatus of the type in which the sugar juice is heated, *in vacuo*, in a coil disposed in a steam-heated chamber, the coil discharging into a reservoir. The principal object of the invention is the construction of an apparatus which will work continuously, and to provide that the reduced pressure in the apparatus shall not be destroyed when a part of the apparatus is disconnected; the apparatus may also be used as a pressure-boiler. An auxiliary chamber is fixed to the reservoir and is connected with an exhaust pump; a three-way tap allows connection to be made between the coil and the reservoir, or the auxiliary chamber and the pump, and means are provided for making an air-tight joint at the

discharge outlet of the chamber. The exhaust pump is always in connection with the coil and the reservoir by means of a column in which is placed a condenser, so that water and other condensed matters can be readily removed.

—W. P. S.

Woody and vegetable substances; Method for the saccharification of — and the recovery of by-products, etc. E. Bouchaud-Praceiq. Fr. Pat. 393,336, Oct. 22, 1907.

THE material, such as woody matter, sawdust, twigs, etc., is finely divided and heated with dilute sulphuric acid to a temperature of about 140° C., the quantity of actual sulphuric acid added being about 5 per cent. of the weight of the material. The treatment lasts for from two to three hours, after which time the acid liquor is removed and the residue is washed and dried. This residue is next treated with its own weight of concentrated sulphuric acid for 24 hours and the solution is then mixed with the acid liquor first obtained. The solution is divided into two parts, one of which is used for treating a fresh batch of material, whilst the second is neutralised by the addition of calcium carbonate or calcium phosphate (natural phosphate). The calcium sulphate is removed by filtration, and, if phosphate has been used, the addition of a further quantity of calcium carbonate results in the precipitation of calcium phosphate, which is removed. The saccharine solution obtained is employed for the production of alcohol or sugar (glucose), whilst the calcium sulphate is converted into calcium sulphide, and the latter is used for the manufacture of sulphur, sulphurous acid or sulphuric acid. The calcium phosphate recovered can also be utilised.—W. P. S.

Amorphophallus roots and tubers; Process for rendering insoluble the mucilaginous substances contained in —. Mertens und Co., Ges.m.b.H. Fr. Pat. 393,426, Aug. 18, 1908.

THE roots or tubers of amorphophallus plants (*Araceæ*), or the mucilage obtained from them, are treated with a solution of sodium hydroxide. The liquid obtained coagulates on continued stirring, and, if spread over the surface of fabrics, forms a water-tight and air-tight coating on the latter. Alkali carbonates, sodium acetate, and copper-ammonium sulphate may be used in place of sodium hydroxide.—W. P. S.

Malt; Decrease of the albumin-content of — on digestion at low temperatures. J. J. van Hest. Z. ges. Brauw., 1908, 31, 645—647.

THE results of the experiments recorded show that whilst the total amount of nitrogen in a malt solution (wort), which has been obtained by digesting the malt for 15 hours at a temperature of 17° C., is about twice as large as that in an undigested extract, the digestion diminishes the amount of albumin and xanthine bases in the solution by approximately one-half. The saccharified digested wort also contains more total nitrogen, less albumin and xanthine bases, and more ammonia than the saccharified undigested wort.—W. P. S.

Diastase and catalase; Adsorption of — by colloidal protein and by normal lead phosphate. A. W. Peters. J. Biol. Chem., 1908, 5, 367—380.

TWO processes for the isolation and purification of diastase and catalase are described. It is possible to purify aqueous extracts of enzyme-containing material from contaminating protein, carbohydrates, and other

matter by the addition of an equal volume of pure acetone. An acetone extract of dried germinated wheat contained only diastase, but the residue possessed catalytic activity. Catalase is thus insoluble in but not destroyed by this reagent. In practice an equal volume of acetone is added to the aqueous enzyme extract and the mixture warmed at 40° C. for a short time. A heavy precipitate formed under these conditions will probably contain most of the enzymes. A 10 per cent. solution of precipitated Witte peptone in 50 per cent. acetone may be applied for the adsorption of diastase and catalase from liquids, these being treated with an equal volume of acetone and 10 c.c. of the peptone suspension. The precipitate containing the adsorbed enzyme is removed by decantation or by means of the centrifuge and can be digested in water when it is desired to test the activity of the adsorbed enzyme. The enzyme is concentrated by this method but becomes associated with the peptone. A lead phosphate suspension, made by precipitating lead acetate with sodium phosphate, likewise precipitates enzyme from aqueous extracts; it has a marked effect in concentrating the enzyme in dilute solutions. Lead phosphate accelerates diastatic action. Appreciable amounts of enzyme can be extracted from the lead phosphate precipitate with water or 50 per cent. glycerin. —E. F. A.

Beer infection [in breweries]: The action of light on —. S. Armstrong. J. Inst. Brewing, 1908, 14, 571–585.

The author describes the case of a brewery in India, which produced porter of excellent quality, but which experienced, over a long period of years, great difficulty in brewing pale ales. The ales almost invariably developed a turbidity and sulphuretted hydrogen "stench," which gradually worked off, leaving the beer flat and sour. It was ultimately noticed that the ale was of good quality only when the time of brewing was accidentally so adjusted that the wort came on the cooler after sunset, and when this was made a regular practice all the previous trouble disappeared. The author's explanation of this phenomenon is that the action of light favoured the development of the spores of air-borne wild yeasts in the wort on the cooler and that the abnormal fermentation was started by these organisms before the pitching yeast could assert its predominance. The author has carried out a number of experiments in the laboratory which tend to confirm the above hypothesis. Working with a darkened chamber affording every opportunity for aerial infection, his experiments led him to conclude that, whereas light has no action on the development of vegetative yeasts, the desiccated resting forms, which are carried in the air, cannot develop without the stimulus of light. The same rule apparently applies to some of the putrefactive and acid-forming bacteria, but the spores of mould fungi, on the other hand, readily develop in the dark. —J. F. B.

Fluorides: Detection of — in beer. J. Flamand. Bull. Soc. Chim. Belg., 1908, 22, 451–453.

The fluoride is precipitated as barium salt from a litre of beer rendered alkaline by addition of ammonia and ammonium carbonate. To assist the deposition of the barium fluoride, an alkali sulphate is added to the beer before addition of the barium chloride. The precipitate is collected, dried (unwashed), and ignited in a platinum crucible. Pure sulphuric acid is added to the crucible, which is immediately covered with a piece of glass coated with paraffin wax through which lines have been drawn. The whole is then placed on the water-bath for one hour, the wax on the glass being kept from melting by covering the upper side with filter paper on which water is constantly dripping. In this way the presence of one mgrm. of ammonium fluoride can be recognised. R. L. S.

PATENTS.

Waste liquors of breweries and distilleries: Process to extract yeast from — to render them suitable for treatment by any process of sewage disposal. W. Hampton, Mortlake. Eng. Pat. 13,811, June 30, 1908.

SAND, sawdust, brewers' or distillers' waste, spent grains, or, preferably, spent or waste hops, are placed in the

revolving cage or hopper of a centrifugal hydro-extractor and forced on to the interior surface of the cage by revolving the latter. The liquor with the yeast in suspension is now fed continuously or intermittently into the cage. The liquor which passes through is fairly free from yeast and is suitable for treatment by a septic, bacterial, or precipitation process of sewage disposal. —T. H. P.

PATENTS.

Milk and process of manufacturing it. J. A. Wülling. Fr. Pat. 393,317, Aug. 6, 1908. Under Int. Conv., Jan. 27, 1908.

MILK-ALBUMIN is dissolved in a solution containing 60 grms. of sodium hydroxide for each kilo. of the albumin. The excess of sodium hydroxide is then removed by dialysis or by neutralisation, and the solution is sterilised. This solution is added to cow's milk to which the requisite quantities of cream, lactose, and water have been previously added, but the quantity of water employed is reduced according to the amount introduced by the solution of albumin. From 3 to 6 grms. of actual albumin are added to each litre of milk. —W. P. S.

Milk for infants: Method for making —. P. Bergell and J. A. Wülling, Berlin. Eng. Pat. 12,516, June 10, 1908.

(B).—SANITATION; WATER PURIFICATION.

Typhoid bacillus: Examination of samples of raw Thames, Lee, and New River water for the presence of the —. A. C. Houston. Metropolitan Water Board. Second Report on Research Work, Oct., 1908. (See also this J., 1908, 873).

THE chief epidemic diseases liable to be water-borne are held to be cholera, typhoid fever, and diarrhoea. With the object of detecting the presence of the typhoid bacillus, eight series of experiments, extending over a period of twelve months, were made with 156 samples of raw river water. The total amount of water dealt with was 29,400 c.c. containing a total of 135,687,500 bacteria capable of growing on gelatin. By cultivation on special media, 7329 colonies were isolated as possible typhoid colonies, but on applying verification tests the whole of these were excluded as not those of the typhoid bacillus. These negative results for a "specific definitely dangerous" pollution fortify a favourable judgment as to the non-specific biological quality of the water. —J. H. J.

PATENTS.

Sterilisation of liquids: Apparatus for the —. H. J. Wessels, Paris. U.S. Pat. 906,975, Dec. 15, 1908.

A VERTICAL cylinder is divided into compartments by a series of plates having capillary perforations. The liquid to be sterilised will not pass through the perforated plates and is maintained at a definite level in each compartment by means of vertical pipes down which the liquid overflows into the next lower compartment. The liquid which overflows is received in a cup surrounded by a cylinder with open ends, by which it is delivered near the perforated plate of the lower compartment. Gas and liquid inlets and outlets are provided at the top and bottom of the vertical cylinder. The gas under slight compression passes through the perforated plates continuously, leaving the apparatus at the top. —J. W. H.

Sewage, waste-water, etc.; Apparatus for the extraction of grease from —. Ges. f. Abwässerklärung m.b.H. Fr. Pat. 333,172, Aug. 10, 1908.

THE apparatus is a kind of trap and consists of a chamber provided with a removable perforated cover; two partitions extend across the chamber but do not reach to the top or bottom, and an inclined cover is placed over the space between these partitions. The sewage, etc., to be freed from fat is passed through the perforated cover on to the inclined plate, which directs it into the space between the outer wall and one of the partitions; passing under the latter, the fatty matter rises and collects in the space between the two partitions, whilst the water flows under the second partition and leaves through an opening at the upper part of the wall of the chamber. The fatty matter is removed as required by raising both the covers, and heavy particles, separating from the sewage, are collected in a removable vessel contained in a well at the bottom of the chamber.—W. P. S.

XIX.—PAPER, PASTEBOARD, &c.

Mineral loading materials for papermaking; Normal characters of —. E. Belani, Papier-Fabrikant, 1908, 6, 2826—2828, 2881—2883, 2941—2945.

THE author describes a photometric method for the estimation of the "whiteness" of opaque minerals, such as kaolin, gypsum, "blanc fixe" or "satin white," suitable for the surface-coating of paper. The mineral is either itself cut into the form of a triangular prism or is spread on the face of a wooden prism, and the amount of light reflected from an electric lamp by the face of the prism on to a movable photometric screen is measured. From the examination of a large number of samples, the author is able to put forward certain values which he regards as normal for various qualities. *Kaolin*.—On suspending in water and passing through a sieve with holes of 0.1 mm., the best English clays, suitable for paper-coating, should leave no residue of sand or mica. Bohemian clays leave 0.1—0.4 per cent. of residue; clays of fair quality for loading in the engine may leave 2—3 per cent. of residue. The loss of moisture at 100° C. is very variable. The author has found for Styrian clays, 0.8—0.9 per cent.; for Bohemian clays, 0.5—5 per cent. for the product from one pit and 7.2—11.2 for that from another; he regards 5 per cent. as a normal maximum for Continental clays. English paper-coating clays contain more moisture, e.g., 12.0—19.8 per cent., but anything over 12 must be regarded as unreasonable. The loss on ignition of the dried clay

is 12 per cent. on the average; there appears to be a connection between the loss on ignition and the "greasy" character of the clay. Some comparative measure of the plasticity of samples of clay is desirable, such as is afforded by sinking a weight into a paste of the clay or by determining the sedimentation-volume, the medium in both cases being 50 per cent. aqueous glycerin. The yield of clay in the paper is about 65 per cent. of the quantity added. *Talc*.—This should be as free as possible from mica, the glittering particles of which may be discerned by spreading a coat of the mineral on a flat surface and examining in a double illumination from two directions. The size of the largest particles of the talc, measured under the microscope, should not exceed 20 μ in diameter. The moisture expelled at 100° C. should not exceed a few units per cent. The loss on ignition was found to be 4.3 per cent. for Styrian and 3.7 per cent. for Pyrenean talcs; 4 per cent. is normal. The amount retained in the paper is about 75 per cent.; in this connection the qualities of low specific gravity (1.6—1.7) are preferable. *Asbestos*.—If microscopic examination show the presence of other forms than thin rodlets, the purity of the sample is to be suspected. The average length of the particles is 80 μ ; the mineral should not be ground too fine. The American product loses 1.3 per cent. of moisture at 100° C.; the loss on ignition ranges from 5 to 7.4 per cent.; normal, 5.5 per cent. The amount retained in the paper is about 70 per cent. *Gypsum*.—The ground native mineral has the form of plates, a maximum diameter of 15 μ being normal. The precipitated mineral occurs as needles, which should not be ground too fine. The loss on ignition of the calcined mineral is 0.5—2.0 per cent.; that of the precipitated is 21 per cent. The amount retained in the paper is about 70 per cent. (calculated as hydrated on anhydrous). *"Blanc fixe"*.—The normal moisture in the paste is 20—25 per cent.; pastes containing up to 50 per cent. are met with but are not normal. *"Satin white"*.—The normal paste contains 34 per cent. of dry mineral.—J. F. B.

Hydrocellulose; Formation of — by means of sulphuric acid. G. Büttner and J. Neuman. Z. angew. Chem., 1908, 21, 2609—2611.

WHEN cellulose is treated with diluted sulphuric acid, of sp. gr. 1.353—1.53, a mixture is formed consisting probably of hydrocellulose and oxycellulose together with unchanged material. Under special conditions (using acid of only 3—4 per cent. strength), however, cellulose hydrates are formed of the general formula, $(C_6H_{10}O_5)_x.H_2O$, (three preparations were obtained in which $x=2, 3$, and 6). Hydrocellulose of this composition, whether $x=2, 3$, or 6, is a white, sandy powder extremely resistant towards acids and alkalis. It is usually not changed by boiling with dilute sulphuric acid, but further experiments are necessary in order to ascertain whether the one stage of hydration may not be changed into another by this treatment. It is dissolved by cold concentrated sulphuric acid or fuming nitric acid, but it is only coloured yellow on boiling with caustic potash or soda. It is also soluble in an ammoniacal solution of copper oxide. When hydrocellulose is treated with acetic anhydride, and concentrated sulphuric acid added, a vigorous reaction ensues and the substance dissolves. On dilution with water an acetyl derivative is precipitated in white to blue opalescent flocks. Hydrocellulose is coloured blue with zinc chloride-iodine reagent or iodine and potassium iodide solution and it reduces Fehling's solution and ammoniacal silver nitrate. Girard's statement that hydrocellulose is readily oxidised even at 50° C. cannot be maintained, for the pure substance remains unchanged at 100° C. If, however, traces of sulphuric acid are present, it is soon decomposed on warming.—J. C. C.

PATENTS.

"Bagasse"; Treatment of — [for obtaining phos]. T. J. Hutchinson, Manchester, and United Railway and Trading Co., London. Eng. Pat. 20,266, Sept. 11, 1907.

"BAGASSE," preferably in a fresh condition, is boiled for about an hour at a temperature not much above 100° C. with a solution containing about 10 per cent. of sodium carbonate calculated on the air-dry weight of the material. Caustic soda or a mixture of the two forms of alkali may

be used if preferred. The operation is better performed in two stages, boiling for half an hour each time with a portion of the prescribed quantity of alkali, and washing the material between the two stages. The most suitable form of digester is one of the "vomiting" type, which causes the liquid to flow through the mass in one direction only without disturbing the fibres. The product of this so-called "mild" treatment will not yet have reached the condition of a "half-stuff"; the fibres are not separated one from another, but the gummy and other impurities of the cane are converted into a soluble form so that they can be eliminated by washing. — J. F. B.

Paper and material therefor ["bagasse"]; *Manufacture of* —. T. J. Hutchinson, Manchester, and United Railway and Trading Co., London. Eng. Pat. 20,267, Sept. 11, 1907.

THE purified "bagasse" fibre, produced by the "mild" treatment described in Eng. Pat. 20,266 of 1907 (see preceding abstract), is subjected to a second and preferably milder treatment of a similar nature, whereby 85–95 per cent. of a paper-making "half-stuff" is obtained from it. In this second treatment the purified "bagasse" fibre is boiled for about one hour under atmospheric pressure with a solution containing 2.5–5 per cent. of caustic soda on the air-dry weight of the material. By this treatment the fibres are sufficiently reduced for conversion into paper pulp by known methods. — J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Strychnine alkaloids, II. A new method for the preparation of sulphonic acids. H. Leuchs and W. Schneider. Ber., 1908, 41, 4393–4395.

STRYCHNINE was mixed with water at 50° C., and sulphur dioxide passed through till the alkaloid was dissolved. Powdered manganese dioxide was then added, and the passage of the gas continued. The liquid was cooled and the crystalline precipitate removed, and recrystallised from water. The substance thus produced is the sulphonic acid of strychnine, $C_{21}H_{22}O_5N_2S$. It crystallises with 4 molecules of water, which are lost on heating to 105° C. It melts with decomposition between 350° C. and 360° C. It crystallises from alcohol and dilute acetic acid in prisms. It is not dissolved by 20 per cent. hydrochloric acid, but dissolves readily in excess of sodium carbonate or hydroxide. A neutral solution when cooled, deposits crystals of the free acid. (See this J., 1908, 640.) — F. SUDS.

Cheiroline, an alkaloid containing sulphur, from wallflower seeds. W. Schneider. Ber., 1908, 41, 4406–4470.

THE name cheiroline is given to the alkaloid found in the extract of the seeds of the wallflower (*Cheiranthus cheiri*). The author finds the alkaloid to have the formula, $C_{29}H_{46}O_2N_2S_2$, his analytical results differing from those of Wagner (this J., 1908, 138). Cheiroline has a neutral reaction, and is optically inactive. When crystallised from ether, it forms handsome colourless prisms melting at 47°–48° C., and is moderately soluble in hot water. The substance dissolves in cold sodium hydroxide solution, and the solution, when acidified, gives off sulphuretted hydrogen and carbon dioxide. The acid solution was found to contain the hydrochloride of a strong base, $C_{29}H_{46}O_2NS.HCl$, which crystallises from absolute alcohol in colourless, prismatic needles melting at 145–146° C. The free base is crystalline but very deliquescent, easily soluble in water, and moderately soluble in cold alcohol. It does not reduce either Fehling's solution or an ammoniacal solution of silver nitrate. The base appears to be a primary one; the methiodide, $C_{29}H_{46}O_2NSI$, melts at 183° C. — F. SUDS.

Alkaloids; New method for the determination of — by means of potassium-mercuric iodide. G. Heikel. Chem.-Zeit., 1908, 32, 1149–1150, 1162–1163, 1186–1187, 1212–1213.

ALKALOIDS in solution are determined by adding excess of Mayer's reagent (N/20 mercuric chloride with potassium iodide), filtering, and finding the amount of mercuric chloride left in the solution by means of standard solutions of potassium cyanide and silver nitrate. A solution of the alkaloid is made containing 0.1 gram. in 10 c.c. Mayer's reagent is then added to 10 c.c. of the alkaloid solution till there is an excess of about 15 c.c. The liquid is diluted to 100 c.c., shaken well, and filtered, 80 c.c. of the filtrate being retained. To this, 10 c.c. of 10 per cent. ammonia are added, and 10 c.c. of N/20 potassium cyanide solution, which precipitates all the mercury. The mixture is acidified, or neutralised, with dilute sulphuric acid and N/20 silver nitrate added till there is a permanent turbidity. From this titration the amount of mercuric chloride actually precipitated by the alkaloid can be ascertained. The method is sufficiently accurate for many ordinary purposes. It can be used for the determination of the amount of alkaloid in tablets, pills, and fluid extracts. A table is given, showing the weight of alkaloid corresponding to 1 c.c. of N/20 Mayer's reagent and the percentage limits of error. — F. SUDS.

Pyretol, the active principle of insect powder [Pyrethrum flowers]. S. Satō. Pharm. Post, 1908, 41, 22.

PYRETOI, the purified active principle of *Pyrethrum* flowers, is an odourless, non-volatile, light yellow, clear, syrupy, resinoid substance; when applied to the tongue it is tasteless, but later it has a numbing effect. It is insoluble in water and in dilute acids; soluble in ether, alcohol, and light petroleum spirit. The fresh solutions are neutral, but gradually become acid; in a month, the acid value amounts to 14.2, and the ester value to 154.3. Pyretol is soluble in hot alkaline solutions and is re-precipitated by acids, but loses its physiological activity by this treatment. It contains no nitrogen. It is extremely toxic to cold-blooded animals, but is practically without action on warm-blooded animals. — J. O. B.

Essential oils; Constituents of —. Carvenene, $C_{10}H_{16}$, and "pure" terpinene. F. W. Semmler. Ber., 1908, 41, 4474–4479.

THE author points out that the physical constants of terpinene as observed by Wallach (this J., 1908, 997), Harries (Ber., 1908, 41, 2516), and himself (Ber., 1907, 40, 2968) do not exactly agree, more especially those relating to the "increments" of the molecular refraction. He has therefore prepared carvenene from carvenone in order to determine its physical constants. Monochlorocarvenene, $C_{10}H_{15}Cl$, was prepared by shaking carvenone dissolved in light petroleum with phosphorus pentachloride, the temperature being kept low throughout. The substance boils at 95–98° C. at 10 mm., has the sp. gr. 0.994 at 20° C., and n_D^{20} 1.51700. The chloride is easily converted into carvenene, $C_{10}H_{16}$, by reduction with sodium and alcohol. The hydrocarbon boils at 61–63° C. at 10 mm., and at 179.5–180.5° C. at 735 mm.; it has the sp. gr. 0.844 at 20° C., and n_D^{20} 1.49100. The author does not think that carvenene and terpinene are identical. He considers that the "merement" in the molecular refraction is an indication of conjugate double bonds in the ring. — F. SUDS.

Camphor; Complete synthesis of —. G. Komppa. Ber., 1908, 41, 4470–4474.

THE fact that Wallach has recently made camphor from β -pinene (this J., 1908, 1130) has led the author to publish his results on the synthesis of camphor from camphoric acid. Racemic camphoric acid, m. pt. 202–203° C., was converted into the anhydride, and reduced with sodium and alcohol to *r*-campholide, $C_{15}H_{24}O_2$, melting at 211.5°–212° C. (corr.). This was converted into cyanocampholide acid by heating in a sealed tube to 230° C. with potassium cyanide. The product was hydrolysed, when *r*-homocamphoric acid, $C_{11}H_{18}O_4$, was produced, which melted at 231°–232° C. (corr.). The homocamphoric acid was treated with twice the equivalent amount of lime, evapo-

rated to dryness with water, and the residue subjected to dry distillation. The substance obtained was purified, and identified as *r*-camphor.—F. SHDN.

dl-Suprarenine: Resolution of synthetic — into its optically-active components. F. Flächer. Z. physiol. Chem., 1908, 58, 189—194.

SYNTHETIC suprarenine (adrenaline, *o*-dihydroxyphenylethanolmethylamine) is, according to Cushman (Pharm. J., 1908, 668), less active physiologically than the levorotatory natural product, probably owing to the dextrorotatory component being inactive. The author has succeeded in resolving the synthetic product into its optically-active components. The substance was moistened with methyl alcohol and dissolved in a hot solution of a molecular proportion of *d*-tartaric acid in methyl alcohol. The alcohol was distilled off from the solution in a vacuum at 35°—40° C., and the residue inoculated with a small crystal of the acid dextrotartrate of natural suprarenine, in order to induce crystallisation. The crystals were dried in a vacuum, triturated with a small quantity of methyl alcohol, filtered, and the residual acid dextrotartrate of *l*-suprarenine washed with methyl alcohol, and recrystallised from 90 per cent. ethyl alcohol or 95 per cent. methyl alcohol until it melted at 149° C. From the mother liquor, the base was separated, and the acid levotartrate of *d*-suprarenine prepared in a similar manner. The optically-active bases separated from their acid tartrates both melted at 211°—212° C. (uncorr.), and yielded non-crystalline oxalates and hydrochlorides. The levorotatory base is identical with natural suprarenine; its optical rotation in hydrochloric acid solution is $[\alpha]_D = -51.4$, and that of the dextrorotatory base, $[\alpha]_D = +51.88$.—A. S.

Suprarenine, synthetic: Action of —. A. R. Cushman. Pharm. J., 1909, 82, 56—57.

THE author has determined the physiological activity of the synthetic dextro- and levo-suprarenine prepared by Flächer (see preceding abstract). It was found that the levo-modification was equal in power to the natural base, and much more active than the dextro-modification, the relative powers being about 12:1. The relative activity of the new commercial synthetic product (*l*-suprarenine) compared with that of the older commercial substance (*dl*-suprarenine) was found to be about 24:13. It is noted incidentally, also, that *l*-hyoscyamine is about 14 times more active physiologically than *d*-hyoscyamine.—A. S.

Carbon suboxide: New method of preparing —. H. Staudinger and St. Bereza. Ber., 1908, 41, 4461—4465.

WHEN malonyl chloride is heated with metallic oxides (especially silver oxide), carbon suboxide is formed, probably through intermediate formation and decomposition of malonic anhydride. Acid chlorides, reacting on silver malonate, also produce carbon suboxide. Much better yields, however, are given by the reaction of zinc on dibromomalonyl chloride in ethereal solution. If ethyl acetate be used as the solvent, the yield is only 40—50 per cent. of the theoretical, against 80 per cent. in the case of ether; but the suboxide formed is much more easily separated from the less volatile ethyl acetate than from ether.—J. T. D.

Hydriodic acid: Method for the extemporaneous preparation of —. G. Heikel. Amer. J. Pharm., 1908, 80, 581—582.

A SOLUTION of ferrous iodide is treated with a slight excess of pure barium carbonate, and the mixture is boiled for 3 to 6 hours, until the addition of ammonia to a portion of the liquid produces only a slight precipitate, which does not diminish on boiling. The mixture is then filtered, the filtrate is allowed to stand for a few hours, and again filtered. It should then be free from iron; if not, it must be boiled again with a little barium carbonate. The solution of barium iodide is then diluted to a definite volume, and the amount of that salt determined in an aliquot part. The exact equivalent of dilute, 10 to 20 per cent., sulphuric acid is then added, to precipitate the barium. To ensure the absence of barium a very

slight excess of sulphuric acid may be used. After removing the barium sulphate, the hydriodic acid solution is concentrated to the desired strength, any iodine liberated during the process being removed by boiling for a few minutes with a small quantity of hypophosphorous acid.—J. O. B.

Hypophosphorous acid: Method for the extemporaneous preparation of —. G. Heikel. Amer. J. Pharm., 1908, 80, 583—584.

THE high price of barium hypophosphite renders it a costly source for the direct preparation of hypophosphorous acid. The acid is more economically obtained as follows: Calcium hypophosphite, in solution, is precipitated with a slight excess of ammonium oxalate; the calcium oxalate is filtered off, and the filtrate boiled with excess of barium carbonate until all ammoniacal odour has disappeared; this should be done with strong solutions, but avoiding evaporation to dryness. The product is treated with a large volume of water and the precipitate is filtered off. The amount of barium in the concentrated filtrate is then determined, and the calculated quantity of dilute sulphuric acid, in slight excess, is added to the hot solution. The precipitated barium sulphate is removed by filtration. Hypophosphorous acid thus obtained should be free from any trace of barium, and contain only a trace of free sulphuric acid.—J. O. B.

Bismuth subsalicylate: Method for the extemporaneous preparation of —. G. Heikel. Amer. J. Pharm., 1908, 80, 584—586.

METALLIC bismuth, or the subnitrate, is dissolved in the smallest possible quantity of nitric acid. Into this solution, a solution of ammonium salicylate is slowly poured, in the proportion of 3 mols. of salicylic acid to one equivalent of bismuth, both solutions being kept cold. At first, free salicylic acid is liberated, and then loosely combines with the bismuth. Ammonium salicylate is then added until no further precipitation occurs. The precipitate is washed twice with cold water, and boiled with successive portions of water until the washings cease to give an acid reaction with litmus paper. The salt is then collected, and dried at a low temperature.—J. O. B.

Cerium and other rare elements: Determination of — in rocks. M. Dittrich. See XXIII.

PATENTS.

Dioxyphenylethanolamines [Dihydroxyphenylethanolamines]; Manufacture of —. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Höchst-on-the-Maine, Germany. Eng. Pat. 9680, May 4, 1908. (Compare this J., 1907, 1028; 1908, 1177.)

By treating dihalogen derivatives of 3:4-methylenedioxytyrol with phosphorus pentachloride, and decomposing the products by means of water, 3:4-dihydroxytyrol-bromohydrin and chlorohydrin are obtained and these react with primary amines or ammonia yielding 3:4-dihydroxyphenylethanolamines.—T. H. P.

p-Aminophenylarsinic acid: Manufacture of homologues of —. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst-on-the-Maine, Germany. Eng. Pat. 14,937, July 14, 1908. Under Int. Conv., July 19, 1907.

THE process consists in heating the arsenate of *o*- or *m*-toluidine or *p*-xylydine with an excess of the base, the compound obtained being amino-*o*-tolylarsinic acid,

$\text{CH}_3\text{C}_6\text{H}_3(\text{NH}_2)\text{AsO}(\text{OH})_2[\text{CH}_3\text{C}_6\text{H}_3(\text{NH}_2)\text{AsO}(\text{OH})_2]_n$ —
1:2:5], m.p. 194—195°, amino-*m*-tolylarsinic acid [1:3:6], m.p. 189°, or amino-*p*-xylylarsinic acid, $\text{NH}_2\text{C}_6\text{H}_4(\text{CH}_3)_2\text{AsO}(\text{OH})_2[\text{CH}_3\text{C}_6\text{H}_3(\text{NH}_2)\text{AsO}(\text{OH})_2]_n$ —
1:4:2:5], m.p. 215° C.—T. H. P.

Acyl derivatives of aminoarylsaric acids: Process of making new —. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 392,857, July 31, 1908. Under Int. Conv., Aug. 19, 1907.

NEW derivatives of arylarsinic acids are obtained by the action of cyanic acid, thiocyanic acid, or their salts or esters on aminoarylsaric acids; thus, by the

action of potassium cyanate and acetic acid on *p*-aminophenylarsinic acid, carbaminophenylarsinic acid, $\text{NH}_2\text{CO.NH.C}_6\text{H}_4\text{AsO}_3\text{H}_2$, is formed.—T. F. B.

Carboxylic acids of acylaminophenyl- and -tolylarsinic acids; Process for preparing —. Farbwerke vorm. Meister, Lucius, and Brüning. Ger. Pat. 203,717, Aug. 15, 1907.

HOMOLOGUES of *p*-acylaminophenylarsinic acids, when oxidised, are converted into carboxylic acids of *p*-acylaminophenyl- or -tolylarsinic acids, which are less toxic in their action than the acids which contain no carboxyl group.—T. F. B.

Bornyl oxalate from pinum; Preparation of —. Chem. Fabr. auf Actien vorm. E. Schering. Fr. Pat. 393,175, Aug. 19, 1908. Under Int. Conv., Aug. 24, 1907.

PINENE is heated with anhydrous oxalic acid in the presence of certain anhydrous chlorides, capable of acting as catalysts, with the addition of a diluting agent. For instance, 100 parts of oil of turpentine are dissolved in 200 parts of carbon tetrachloride, and the liquid is heated to 50° C. An intimate mixture of 50 parts of anhydrous oxalic acid and 5 parts of aluminium chloride is then added in small portions at a time. The mass is maintained at a temperature not exceeding 70° C. for two or three hours, and the bornyl oxalate is isolated in the usual manner.—J. F. B.

Camphor from oil of turpentine; Preparation of —. A. Mayer. Fr. Pat. 393,504, Aug. 24, 1908.

THE solid modification of the pinene hydrochloride obtained from oil of turpentine is heated with the oxide of an alkaline-earth metal, in presence of excess of an acid of the fatty series. If an acid of low molecular weight be used, the camphene which is at first produced is esterified, with the formation of the bornyl and isobornyl esters of the acid employed; these must then be saponified. If one of the higher fatty acids be used, camphene is the sole product of the reaction. The camphene, borneol, or isoborneol is then converted into camphor by oxidation in the usual manner.—J. F. B.

Scandium or scandium compounds; Preparation of from minerals. R. J. Meyer. Ger. Pat. 202,523, March 15, 1908.

FOR the separation of scandium from minerals, the residue left after lixiviating the reaction product of the usual fusion process, is neutralised with acid, and treated with such a quantity of oxalic acid or hydrofluoric acid that the scandium is precipitated, whilst iron and manganese remain in solution. The precipitated scandium oxalate may be ignited, the residual oxide dissolved in hydrochloric acid, and scandium reprecipitated with hydrofluoric acid. Example: 100 kilos. of the residual oxides left after lixiviating the reaction product from the fusion of wolframite are dissolved in 250 kilos. of crude hydrochloric acid, and to the filtered solution a concentrated solution of 80 kilos. of oxalic acid is added. The precipitate is collected after 24 hours, washed, dried, and ignited. The residue is dissolved in hydrochloric acid, the solution neutralised with ammonia or magnesia, and treated with hydrofluoric acid until the liquid becomes colourless. After warming, the precipitate is collected, washed, and decomposed with concentrated sulphuric acid. The soluble sulphates are extracted with water, and the scandium precipitated from the solution by an excess of oxalic acid. A yield of 300–400 grms. of scandium oxide of 90–95 per cent. purity is stated to be obtained.—A. S.

Bismuth salt of paraneleic acid; Process for preparing the —. G. Richter. Ger. Pat. 202,955, April 28, 1907.

CALCIUM paraneleinate is decomposed by a soluble, inorganic bismuth salt, in saturated sodium chloride solution; the bismuth paraneleinate thus obtained is said to contain 50 per cent. of bismuth.—T. F. B.

**o*-Nitrobenzonitrile and *o*-nitrobenzamide from *o*-nitrobenzaldehyde; Preparation of —.* Kalle und Co. Ger. Pat. 204,477, Nov. 13, 1907.

ALTHOUGH aldoximes are usually converted into nitriles only in presence of dehydrating agents, *o*-nitrobenzaldehyde is converted into *o*-nitrobenzonitrile by heating in dilute aqueous solution with dilute alkalis (e.g., sodium carbonate, borax, potassium cyanide, etc.). 15 kilos. of *o*-nitrobenzaldehyde are boiled with 0.6 kilo. of potassium cyanide and 150 litres of water under a condenser, for nine hours; on cooling, pure *o*-nitrobenzonitrile crystallises out. If 20 kilos. of the oxime are boiled for nine hours with 1.6 kilos. of crystallised sodium carbonate and 200 litres of water, *o*-nitrobenzamide separates from the solution on cooling.—T. F. B.

Glucose and sodium iodide; Process for preparing a crystalline double compound of —. J. A. Wülling. Ger. Pat. 204,764, March 29, 1907. Addition to Ger. Pat. 196,605, March 16, 1907 (this J., 1908, 471).

THE double compound of glucose and sodium iodide described in the original patent can also be prepared by using, in place of ethyl alcohol, other indifferent solvents, such as methyl alcohol, acetone, etc.—T. F. B.

Glycollic acid; Process for preparing — by electrolytic reduction of oxalic acid. Deuts. Gold- und Silber-Scheide-Anstalt vorm. Rössler. Ger. Pat. 204,787, Dec. 11, 1903. Addition to Ger. Pat. 194,038, Dec. 6, 1903 (see U.S. Pat. 837,083; this J., 1907, 157).

HYDROCHLORIC acid (20 per cent., or sp. gr. 1.1) can be used in place of sulphuric acid as electrolyte for the electrolytic reduction of oxalic acid, carbon being used as anode; otherwise the process is carried out as in the original patent.—T. F. B.

Oxalates; Process for the preparation of — from formates. Elektrolytische Werke Ges.m.b.H. Ger. Pat. 204,895, Oct. 14, 1906.

FORMATES are converted into oxalates by heating in a vacuum at a temperature below 360° C.—A. S.

Allophanic acid santalol ester; Process for preparing —. Verein. Chimmfabr. Zimmer und Co. Ger. Pat. 204,922, Aug. 31, 1907.

THE santalol ester of allophanic acid, which melts at 162° C., is tasteless and odourless, and contains about 72 per cent. of santalol, is obtained by any of the usual methods of making allophanic esters, e.g., by the prolonged action of cyanic acid on santalol in presence of benzene or other solvent, or by the action of urea chloride, phenol carbamate, or phenol allophanate on santalol.—T. F. B.

Radioactive preparations and apparatus for use thereof. A. J. Boulton, London. From Radiogen Ges.m.b.H., Charlottenburg, Germany. Eng. Pat. 27,735, Dec. 16, 1907.

SEE U.S. Pat. 907,066 of 1908; this J., 1909, 41.—T. F. B.

Santalol ethers and intermediate compounds [santalol halides] for use therein; Manufacture of —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 4930, March 4, 1908.

SEE Ger. Pat. 202,352 and 203,882; this J., 1908, 1177 and 1223.—T. F. B.

Ortho- and para-chlorobenzaldehyde; Process for the separation of —. O. Imray, London. From Farbenwerke vorm. Meister, Lucius, und Brüning, Höchst am Main, Germany. Eng. Pat. 9107, April 27, 1908.

SEE Fr. Pat. 389,750 of 1908; this J., 1908, 1041.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Colour photography. A new multicolour grating. F. Limmer. Z. angew. Chem., 1909, 22, 14.

THE objection to Lumière's autochromatic plate is its low degree of sensitiveness, due to the opacity of the coating. A new three-colour grating by Szezepanik does not suffer from this defect. He makes use of the observation that colours are able to transfer themselves from one vehicle to another; thus, when a collodion film coloured red with erythrosin, is superimposed upon a colourless gelatin film, the dyestuff transfers itself almost completely from the collodion to the gelatin. In general, it appears that basic dyestuffs have a "preference" for collodion, and acid dyestuffs for gelatin. Szezepanik prepares three solutions of gelatin and colours them with suitable dyestuffs, which have a "preference" for collodion. The solutions are evaporated to dryness and the residues finely powdered; they are mixed, and the mixture dusted over collodion plates which are still somewhat soft. The dyestuffs wander from the gelatin powder in contact with the collodion film, and produce in the latter a mosaic of minute, coloured areas, which correspond to the coloured starch grains of the autochromatic plate. The almost colourless gelatin powder is then washed away. The Szezepanik grating is much more sensitive to light than the autochromatic plate, and yields pictures of greater brightness and brilliancy.—F. M.

Development with pyrogallol; *Correction of over- or under-exposure in* —. A. and L. Lumière and A. Seyewetz. Bull. Soc. Franç. Phot., 1908, 24, 488—491.

THIS method is based on the variation of the amount of alkali in the developer, as well as the time of development, according to the degree of under- or over-exposure. The following solutions are prepared:—(a). Pyrogallol, 30 grms.; sodium bisulphite solution ("commercial"), 10 c.c.; water, 1000 c.c. (b). Sodium carbonate, 35 grms.; anhydrous sodium sulphite, 75 grms.; potassium bromide, 5 grms.; water, 1000 c.c. 10 c.c. of (a), 20 c.c. of (b), and 90 c.c. of water constitutes the normal developer. In order to increase the time for the first appearance of the image, only 10 c.c. of (b) are used at first; according to the time taken for the image to appear, also having regard to the rapidity of the plate used, further quantities of (a) or (b) are added, these quantities and the total duration of development being found from a table: the time of development for exposures varying between eight times normal or one-fourth normal, is between 12 and 18 minutes.—T. F. B.

Toning-fixing process after fixing [for photographic papers]. R. Namias. Eders Jahrbuch, 1908, 72. Z. angew. Chem., 1909, 22, 28.

SINCE the instability of silver prints, toned in the combined bath containing sulphur, is attributed to the presence of

silver thiosulphate in the bath, it is proposed to immerse the prints, before toning-fixing, in a solution of thiosulphate, preferably containing boric acid.—T. F. B.

Prints on silver chlorocitrate paper, toned and fixed in one operation; *The alteration of* —. A. and L. Lumière and A. Seyewetz. Bull. Soc. Franç. Phot., 1908, 24, 481—483.

A NUMBER of prints on silver chlorocitrate paper, toned and fixed in the combined bath, were kept in a damp place for seven years; after that time it was found that none of the prints toned and fixed in solutions containing gold salts, whether in presence of lead salts or not, had deteriorated if they had been perfectly washed; prints toned in solutions containing lead salts alone, without gold, as well as prints which had been insufficiently washed, showed marked deterioration. The presence of lead in the finished print appears to have no effect on the stability of the image, but the substitution of tin for lead in the combined bath gave unfavourable results in this respect.—T. F. B.

Photocyanide and photothiocyanate. Lüppo-Cramer. Eders Jahrbuch, 1908, 15. Z. angew. Chem., 1909, 22, 28.

SILVER photocyanide and photothiocyanate were obtained in the same way as the photohalides, *viz.*, silver hydrosols were mixed with hydrosols of silver cyanide or thiocyanate, and the gel precipitated by concentrated sulphuric acid; when purified from free silver by treatment with nitric acid, the photocyanide was obtained as a rose-red and the photothiocyanate as a brick-red body. The former soon became blue-violet when exposed to the light, but the latter was very little altered.—T. F. B.

PATENTS.

Celluloid; *Colouring* —. more especially for use in preparing coloured screens for photography. F. Lehner, Zürich, Switzerland. Eng. Pat. 7629, April 6, 1908.

ALL the dyestuffs hitherto used for colouring transparent celluloid have been soluble in strong alcohol and have possessed the disadvantage of allowing "spreading" of the colour beyond its own limits when used for multicolour screens. According to this invention certain dyestuffs, which are enumerated, are used which are readily soluble in water but as far as possible insoluble in alcohol. The celluloid is milled with alcohol diluted with as much water as possible, and the dyestuffs, either solid or in aqueous solution, are incorporated with the plastic mass. When this is homogeneous it is reduced to films which are then dried very slowly. Finally the films are softened by exposure to the vapour of alcohol and the process of rolling is completed.—J. F. B.

Celluloid films for photography; *Process and apparatus for applying emulsions to* —. Soc. Civile des Pellicules Nouvelles pour Cinématographes et autres usages. Fr. Pat. 393,224, Oct. 19, 1907.

A NUMBER of plates with plane surfaces, mounted on wheels, are joined together to form an endless band, which passes over a vacuum chamber containing water-cooled tubes: each plate is perforated with a number of holes. A band of celluloid is led on to the chain of plates, and is given a velocity equal to that of the plates; just after it passes over the vacuum chamber, where it is held in close contact with the plates, a stream of emulsion is made to flow on to it; it then passes beneath hoods containing cold water, and finally to the drying apparatus.—T. F. B.

Photography of colours; *Trichromatic screen for the* —. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. Fr. Pat. 393,296, Oct. 21, 1907.

A GLASS or other screen is coated with a layer of gelatin, etc., which is then stained with one of the colours to be used; a series of parallel lines, covering about one-third of the surface, is now ruled in a fatty ink on the gelatin, and the exposed dyed gelatin decolorised and stained with a second colour; a second series of lines, perpendicular to the first, and covering one-half of the stained surface exposed, is ruled on the gelatin with ink, and the

decolourisation repeated, the remaining spaces being stained with the third colour. On removing the fatty ink by washing with a suitable solvent, a trichromatic screen is obtained which can at once be coated with a sensitive emulsion.—T. F. B.

Gelatin films coated on either side with collodion; Process for preparing — for photographic and other purposes. O. Moh. Ger. Pat. 204,868, Sept. 8, 1906.

A SMALL quantity (e.g., one per cent.) of a neutral soap, in alcoholic solution, is added to the collodion and gelatin solution for making films by applying successive coatings of collodion, gelatin, and collodion to suitably prepared paper or other temporary support. The films can be readily removed from the support, are quite clear, do not readily crack or ignite, and can easily be coated with a sensitive emulsion.—T. F. B.

Silver salt [photographic] copying papers. Chem. Fabr. auf Actien, vorm. E. Schering, Ger. Pat. 203,373, Jan. 31, 1908.

THE known printing-out papers for producing hard prints, made by addition of ferriyanides, chromates, and chromic acid to the silver salt emulsion, are yellowish in colour, and there is, therefore, a difficulty in judging the correct depth of printing. According to the present invention, white papers giving harsh contrasts are produced by using vanadic acid, vanadates, or complex vanadic acid compounds (e.g., phosphovanadates) in small quantities in preparing the emulsions.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, &c.

PATENT.

Analysis of gases [products of combustion]; Apparatus for the —. J. A. Caldwell, Montclair, N.J. U.S. Pat. 906,687, Dec. 15, 1908.

THE apparatus comprises a measuring chamber into which a charge of furnace gases is drawn, and absorption and displacement chambers, with means for recording on a card the amount of gas absorbed or the amount left unabsorbed. The measuring chamber is connected to each of a number of furnaces in succession, and the result of the analysis is recorded on a separate card for each furnace. The record cards are carried by a movable holder which automatically brings the next card into position, when the measuring chamber is connected to the next furnace.—A. T. L.

INORGANIC—QUANTITATIVE.

Copper; Effect of — on the results of the Zimmermann-Reinhardt method of titrating iron. K. Schröder. Z. öfentl. Chem., 1908, 14, 477—492.

MINUTE traces of copper have the effect of lowering the result of titrating an iron ore; larger quantities give too high a result, while intermediate quantities may be without effect, through opposite tendencies compensating one another. The cause of the lowered results is "induced" oxidation of the iron, partly by the hydrogen peroxide formed during the autoxidation of the cuprous compounds, partly by the reversible reaction, $\text{CuCl}_2 + \text{FeCl}_2 \rightleftharpoons \text{CuCl} + \text{FeCl}_3$. The speed of these oxidising reactions increases as the acid-concentration is diminished. A copper-content of not more than 0.01 per cent. may be neglected in ordinary work, but if more copper than this is present it should be removed before reducing and titrating the iron. No material containing copper should be used as a standard, and the freedom from copper of all the reagents used, especially of the stannous chloride, should be ascertained.—J. T. D.

Cerium and other rare elements; Determination of —, in rocks. M. Dittrich. Ber., 1908, 41, 4373—4375.

CERIUM is completely precipitated from its salts by oxalic acid or ammonium oxalate; if, however, ferrous salts be present, the precipitate is contaminated by iron. If ferric salts be present in considerable quantity, no precipitate is formed at first by oxalate, and only after considerable excess has been added, and the iron has been converted into the complex ferric oxalate, does further addition of oxalate precipitate the cerium. The precipitate so formed is, however, pure and free from iron. For 0.2 gm. of cerium salt and 15 c.c. of concentrated ferric salt, at least 200 c.c. of saturated ammonium oxalate solution must be used. It is best to precipitate in hot solution, as the precipitate is then denser and better to filter. It should be washed at first with ammonium oxalate solution. The allied metals can be separated from iron (aluminium or chromium) in the same way as cerium.—J. T. D.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Silicides of hydrogen. P. Lebeau. Compt. rend., 1909, 148, 43—45.

THE mixture of gases evolved on treating magnesium silicide with hydrochloric acid was submitted to a series of fractionations by means of liquid air (see Moissan and Smiles, this J., 1902, 504). In this way in addition to the gaseous silicides, SiH_4 and Si_2H_6 , small quantities of a liquid and of a solid silicide were obtained. Silicoethane, Si_2H_6 , was obtained in a nearly pure condition; it boils at about -7°C , and is probably quite non-inflammable (spontaneously) in the air when pure. The liquid silicide is probably silicoethylene, Si_2H_4 ; in contact with oxygen it burns with a very bright flame and gives rise to violent explosions.—A. S.

Colloidal suspensions; Behaviour of — with immiscible solvents. W. L. Miller and R. H. McPherson. *J. of Physical Chem.*, 1908, 12, 706—716.

As a rule, attempts to bring about the distribution of a colloid between two immiscible solvents result in the coagulation of the colloid (this *J.*, 1906, 1177). A mixture of chloroform and alcohol (or acetone), however, does not coagulate the hydrosol of arsenious sulphide, although no distribution is observed. If ether or ethyl acetate, on the other hand, be substituted for chloroform, distribution readily occurs, whether the consolute liquid be alcohol, acetone, or propyl alcohol. For example, by mixing a 1 per cent. solution of arsenious acid, ether, alcohol, and hydrogen sulphide solution, in the order given, taking somewhat less alcohol than is necessary to make a homogeneous solution, and then shaking and allowing to stand, two clear yellow layers separate, which may remain for days apparently unchanged. By adding more ether, the volume of the lower layer is diminished and the concentration of the colloid in that layer increased. Colloidal antimony trisulphide also becomes distributed between the two liquid phases in the system, water-ether-alcohol, but a like phenomenon has not been observed with copper sulphide.—F. SODN.

Egg-albumin and acetic acid;] Physico-chemical investigation of the interaction of —. L. Zoja. *Z. Chem. Ind. Kolloide*, 1908, 3, 249—269.

IF acetic acid is added to dialysed albumin solution, the mixture gradually increases in consistence on standing, and finally forms a transparent mass which can no longer be poured out of the test-tube. The presence of salts increases the rapidity with which this occurs. No precipitate is formed, but mixtures containing much acetic acid become slightly opalescent. On warming the jelly dissolves to a perfectly clear solution and gelatinises again on standing. The viscosity of solutions of acetic acid and albumin increases with the time; after any given length of time it increases with the amount of acetic acid originally added, up to a maximum of 7.01 per cent.; it then falls to a minimum at 11.22 per cent. and again rises. The electric conductivity of the mixtures is always higher than that of the corresponding mixture of water and acetic acid only, but the curves are otherwise analogous. The maximum amount of viscosity is only reached after a considerable time, which is never less than 18 to 20 days. Formic acid has a much more rapid and stronger effect than acetic acid, whilst with propionic acid the reverse is the case. The presence of inorganic salts increases the rapidity of reaction, but the maximum viscosity is attained at the same concentration as before. Acetates alone, without free acetic acid, do not effect any increase in the viscosity of albumin solutions.—E. F.

Copper albuminate; Acid and neutral —. G. Bonamartini and M. Lombardi. *Z. physiol. Chem.*, 1908, 58, 165—174.

SOLUTIONS of egg-albumin were treated with varying quantities of copper sulphate solution, with and without addition of varying quantities of potassium hydroxide solution, and the precipitates weighed and analysed. In the absence of potassium hydroxide the precipitates were of practically constant composition, whatever the quantity of copper sulphate added, and contained copper and the sulphuric acid radical (SO_4) in equivalent proportions, the average composition of the precipitate being:—8.07 per cent. of sulphuric acid radical (SO_4); 5.26 per cent. of copper; and 86.67 per cent. of albumin. The amount of the precipitate decreased as the total volume of the reacting liquids increased, and was practically unaffected by the concentration of the copper sulphate when the total volume was unaltered. The authors conclude that under these conditions an "acid compound" is formed, which is considerably soluble in the liquid, and which contains chemically equivalent amounts of copper and sulphuric acid radical (SO_4). When increasing amounts of potassium hydroxide solution are added to mixtures of albumin and copper sulphate solutions, the amount of precipitate formed increases steadily up to the point at which the supernatant liquid is neutral

in reaction. At the same time the amount of copper in the precipitate progressively increases and the amount of sulphuric acid radical (SO_4) decreases. If potassium hydroxide solution is added until the supernatant liquid is neutral in reaction, and the precipitate is washed with distilled water, in which it is then insoluble, the resulting precipitate contains no sulphate, and has the composition:—31.25 per cent. of copper; 68.75 per cent. of albumin. If an excess of alkali is added it is not found possible to filter and collect the resulting precipitates. The authors consider the resulting insoluble compound, free from sulphate, to be a "neutral salt"; it does not froth when shaken up with water, but the acid salt causes frothing when so treated.—E. F.

Peroxydase; New artificial —. E. de Stoecklin. *Comptes rend.*, 1908, 147, 1489—1491. (See also this *J.*, 1908, 185, 474, 772.)

TANNATE of iron, prepared by the interaction of tannin and a ferric salt, acts as a peroxydase capable of transferring oxygen from hydrogen peroxide to a number of compounds, most of which resist the action of all the peroxydases previously known. Thus, alcohol is oxidised to acetaldehyde, and a large number of phenols and phenolic and amino-derivatives readily undergo oxidation. Contrary to what is the case with other peroxydases, tannate of iron acts most readily on monophenols and, in general, on compounds containing only one hydroxyl-group. This peroxydase usually yields oxidation products which resinify, so that its action cannot be compared with that of ferric sulphate and hydrogen peroxide; in the latter case, however, the action seems to be more vigorous than the former. It is interesting to note that this peroxydase attacks tyrosine, for up to the present the peroxydases have been found capable of acting only on compounds which are also oxidised by oxydases of the laccase type and not on tyrosine, which is only attacked by the enzyme tyrosinase; whether the action of the latter on tyrosine yields the same products as that of tannate of iron has not been ascertained.—T. H. P.

Iron and Steel Institute. The Andrew Carnegie Research Scholarship.

A RESEARCH Scholarship or Scholarships, founded by Mr. Andrew Carnegie, will be awarded annually, irrespective of sex or nationality, on the recommendation of the Council of the Iron and Steel Institute, 28, Victoria Street, London, S.W. Candidates, who must be under thirty five years of age, must apply on a special form before the end of February to the Secretary of the Institute.

The object of this scheme of Scholarships is not to facilitate ordinary collegiate studies, but to enable students, who have passed through a college curriculum or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry.

The appointment to a Scholarship shall be for one year, but the Council may at their discretion renew the Scholarship for a further period.

THE PATENTS AND DESIGNS ACT, 1907.

American Letters Patent Revoked. *Times*, Jan. 6, 1909.

THE Comptroller-General of Patents, Designs, and Trade Marks (Sir Cornelius Dalton) has given his decision in an application for the revocation of letters patent under the Patents and Designs Act, 1907. The applicants were William T. Thomson and James Knox, and they applied for the revocation of letters patent No. 26,519 of 1896, on the ground that the patented article is not manufactured to an adequate extent in the United Kingdom. The prime object of the invention protected by the patent was to produce a lockstitch sewing machine capable of operating at a high speed upon either thick or thin work.

It appeared from the evidence that the machine as imported had been wholly manufactured in the United States, but that before it was sold in this country a few parts were taken out and in their place others were substituted which were manufactured here. The substituted

parts, however, were very few in number, as compared with the other patented parts of the machine. It further appeared from the evidence that accessories not the subject of the patent were manufactured in this country, and sold in certain cases with the machine. The machine is not patented in Germany, and the applicants for the revocation of the patent were alleged, in the declaration of the managing director of the company who own the patent, to be, or to be about to become, agents for certain manufacturing firms in Germany and elsewhere for whom they desire to sell sewing machines which are made by such firms in accordance with the patent, and, if at present sold in the United Kingdom, would be an infringement of the patent.

In his decision, the Comptroller-General said that the first question which he had to decide was whether the patented article was manufactured to an adequate extent in the United Kingdom. For the purposes of this question the accessories to the machine, which were alleged to be manufactured in this country, must be disregarded; for it was not suggested that any of them formed part of the invention protected by the patent. It seemed to him impossible to contend that the public demand in this country for the patented article was substantially met by the manufacture here of a comparatively small number of substituted parts, which were mere modifications, made to suit the taste and convenience of certain purchasers, for which there would be no demand except for the purpose of using them as parts of the entire machine. The question that next arose was whether the patentees had given satisfactory reasons why the patented article was not manufactured to an adequate extent in the United Kingdom. The company did not themselves manufacture the machines imported from the United States, but employed for the purpose a firm there, whom they considered the best tool manufacturers in the world. It was easy to understand that they had found it more convenient to continue to employ this firm, on whom they felt they could rely, for such refined work as theirs, than to employ a manufacturer in this country to do it for them, or to set up factories here for the purpose. But their own convenience was obviously of itself no satisfactory reason within the meaning of the section for not manufacturing the patented article in the United Kingdom. An attempt had therefore been made to show that it was impossible to make the machine in this country. It was very natural that the patentees and their *employés* should believe that their machine was a better one than anyone else could produce, and that the American firm which had done their work well for 40 years were the best tool manufacturers in the world. But it was manifest that opinions of this kind must be received with considerable hesitation, having regard to the high-class machinery turned out in this country and on the Continent; and that even if they could be substantiated, they would not, of themselves, afford a satisfactory reason for not manufacturing in the United Kingdom. If he were to accept opinions of this kind as a satisfactory reason for failing to manufacture in this country, he doubted whether any American patent for machinery of precision could be revoked on the application of a German applicant; or any German patent for similar machinery on the application of an American applicant, although, as a matter of fact, the machinery might in both cases very well be manufactured in any one of the three countries, if the patentee were not in possession of the monopoly of manufacture. In the present instance, the patentees evidently regarded with some apprehension the importation of the machine by rival manufacturers in Germany, where it was not patented. It was said that if the patent were revoked "the country would be flooded with German and other Continental imitations of their machines," and that the company did not want to see the public put off with machines which they were convinced were very much inferior to this one. He doubted very much whether the protection which, it was suggested, the users of these machines would derive from the continuance of the patent was quite the kind of protection which they themselves desired or required, and whether they would not prefer that the trade should be freed, and that they should have the opportunity of testing the qualities of some of these

much-maligned German sewing machines, which could not be brought into this country so long as the patent remained in force. The patent had rather less than two years more to run in the ordinary course, and, according to the evidence of the managing director of the company, it would be between five and ten years from the present time before the company could be in a position to make the machine completely in this country. On the other hand, it appeared from the evidence of Mr. Knox that a German firm were able to put a similar machine on the market in six months from the time when they started to make it. If the company's evidence was correct, no useful object would apparently be gained, if he were to make an order revoking the patent after a reasonable interval. On the other hand, if Mr. Knox's evidence was correct, it was possible that if he revoked the patent forthwith the patented article might be manufactured in this country before the time when the patent would expire. The power to defer the revocation for a reasonable interval was given for the protection of patentees who of their own accord had taken substantial preliminary steps to comply with the requirements of the Act, but had not had sufficient time to complete their works and actually manufacture the patented article before an application was made to revoke their patent. Here it appeared that the patentees had taken no steps whatever with a view to meeting the requirements of the section, although more than 16 months had elapsed since the passing of the Act. He therefore ordered, subject to an appeal to the Court, that the patent be revoked forthwith, and that the patentees pay to the applicants in respect of the costs of their application the sum of 40 guineas.

New Books.

TECHNOLOGIE ET ANALYSE CHIMIQUES DES HUILES, GRAISSES ET CÈRES. Par le Dr. J. LEWKOWITZKY, M.A. Traduit du Manuscrit, spécialement rédigé pour cette édition par l'Auteur, par EMILE BONSTORF. Tome II. H. Dunot et E. Pinat, Éditeurs, 49, Quai des Grands-Augustins, Paris. 1909. Price 30 frs.

THE appearance of Volume I. of this work (French edition) was noticed in this Journal, 1906, 1010. It contained 546 pages of subject matter and 53 illustrations. The present volume (Vol. II.) brings up the contents to 1416 pages, with 10 illustrations and a sheet of microphotographic engravings. There are two indexes, *viz.*, a botanic index, and a zoologic index. This portion of the work commences with Chapter XIII., which is principally concerned with the extraction and preparation of the raw materials used in the industries of the oils, fats, and waxes; it then proceeds to Chapter XIV., which is occupied with the general technology of the natural oils, fats, and waxes, their methods of purification and preparation, refining, and examination, with a description of the processes for detecting and determining adulterations. The classification proceeds as follows:—A.—OILS AND FATS. Glycerides I. OILS, OR LIQUID FATS. 1. Vegetable oils. (i.) Drying oils. (ii.) Semi-drying oils. (iii.) Non-drying oils. 2. Animal oils. (i.) Oils of marine animals. (ii.) Oils of terrestrial animals. II. FATS, OR SOLID FATTY BODIES. 1. Vegetable fats. 2. Animal fats. (i.) Drying fats. (ii.) Semi-drying fats. (iii.) Non-drying fats. B.—WAXES. 1. Liquid waxes. II. Solid waxes. 1. Vegetable waxes. 2. Animal waxes.

DIE STEARINFABRIKATION. Von BÉLA LACH, Ph.D. Wilhelm Knapp's Verlag, Halle a. S. 1908. Price M.6.40.

8vo volume, containing 176 pages of subject matter, with 79 illustrations. There is an alphabetical index of authors' names, and one of subject matter. The subject matter is classified according to the following scheme:—I. Raw materials for the stearine manufacture. II. Preparing the raw materials. III. The manufacture of oleomargarine. IV. Refuse fat or kitchen fat. V. Bone

fat or grease. VI. Obtaining fish oils. VII. Obtaining fat from animal carcasses. VIII. Preparation of raw materials. IX. Working up fatty matters for stearine. X. Preparation of fatty acids. XI. Description of the distillation apparatus. XII. Distillation under vacuum, etc. XIII. Hydraulic cold press. XIV. Warm pressing of fatty acids. XV. Selection of the pressed stearine. XVI. The elaine: Its filtration, etc. XVII. Analysis of fatty matters. Simple and rapid method for determining the free fatty acids in mixed fats.

INTRODUCTION TO THE RARER ELEMENTS. By PHILIP E. BROWNING, Ph.D. 2nd Edition. John Wiley and Sons, New York, U.S. America. Price \$1.50 net. Chapman and Hall, Limited, London. 1908. Price 6s. 6d. net.

8vo volume, containing 206 pages of subject matter, an engraving representing the typical absorption spectra of the rare earths, and an alphabetical index. Commencing the book, there is also an index to the literature of certain of the rare elements. The groups treated of in the text are the following:—I. The alkalis. II. Beryllium. III. The radio metals. IV. The rare earths. V. Gallium, indium, thallium. VI. Titanium, germanium. VII. Vanadium, niobium, tantalum. VIII. Molybdenum, tungsten, uranium. IX. Selenium, tellurium. X. The platinum metals; Gold. XI. The rare gases of the atmosphere. XII. Technical applications. XIII. Qualitative separation.

ELEMENTARY AGRICULTURAL CHEMISTRY. A Handbook for Junior Agricultural Students and Farmers. By HERBERT INGLE, B.Sc. Chas. Griffin and Company, Ltd., Exeter Street, Strand, London, W.C. 1908. Price 4s. 6d.

SMALL 8vo volume, containing 241 pages of subject matter, six illustrations, and the alphabetical index. The text is classified according to the following plan:—I. Introduction. Outline of chemical theory. II. The atmosphere. III. The soil. IV. Natural waters. V. The plant. VI. Manures. VII. Crops. VIII. The animal body. IX. The feeding of animals. X. The dairy. XI. Disinfectants and antiseptics. Fungicides. Insecticides. Plant poisons.

FIRST PRINCIPLES OF CHEMICAL THEORY. By C. H. MATHEWSON, Ph.D., Instructor in Chemistry and Metallurgy at the Sheffield Scientific School of Yale University. First edition. John Wiley and Sons, New York, U.S. America. 1908. Price \$1.00 net. Chapman and Hall, Ltd., London. Price 4s. 6d. net.

8vo volume, containing 119 pages of subject matter, seven illustrations, and alphabetical index. The subject matter receives the following classification:—I. Leading principles of general inorganic chemistry. II. Natural classification of the elements. III. Determination of molecular weights. IV. Determination of atomic weights. V. Calculation of formulae. VI. Osmotic pressure and related phenomena with special reference to dilute aqueous solutions of acids, bases, and salts. VII. The electrolytic dissociation theory. VIII. The law of chemical mass action. IX. Heterogeneous equilibrium. X. Thermochemistry.

LABORATORY NOTES ON INDUSTRIAL WATER ANALYSIS. A Survey Course for Engineers. By ELLEN H. RICHARDS, Instructor in Sanitary Chemistry, Massachusetts Institute of Technology. First edition. John Wiley and Sons, New York, U.S. America. 1908. Price 50 cents net. Chapman and Hall, Ltd., London. Price 2s. net.

8vo volume, containing 48 pages of subject matter, and an alphabetical index. The text is planned as follows:—PART I. (i.) Introduction. (ii.)—(vii.) Laboratory exercises. PART II. (i.) Standard solutions. (ii.) Computation of hypothetical combinations. (iii.) Percentage composition of salinity in various waters. (iv.) Convenient data and tables. (v.) Useful references.

TONINDUSTRIE KALENDER. 1909. ERSTER THEIL. ZWEITER THEIL. DRITTER THEIL. Verlag der Tonindustrie-Zeitung, Berlin. N.W. 21. Price for all three parts, M.1.50, without postage. Single parts M.1 each.

Erster Teil.—This takes the form of a pocket-book, bound in water-proof cloth, with calendar and blank pages for notes; pencil, etc. Its table of contents refers to all three parts, though each part forms a separate booklet. It contains besides the calendar and note pages, also a couple of pages of data furnished by Seger and Cramer with respect to the Seger cones, and their uses, etc. There is also a sheet with the molecular weights of the most important substances for the clay industry, data as to saturation capacity of the atmosphere for moisture, and mean values of the fusion points of Seger cones.

Zweiter Teil.—This little volume contains 392 pages, and an alphabetical index. There are 147 illustrations. All data and constants are furnished for the clay and earthenware chemist, as regards clays, fuels, etc., also as regards furnaces, mills, and apparatus generally, directions and data are given.

Dritter Teil.—This part is an index or guide to the best books and sources of information for the clay worker and chemist. Classified lists are also given of the best firms where materials, apparatus, and utensils, etc., can be obtained, most likely to be useful to the clay worker, potter, etc.

STATISTICAL TABLES RELATING TO BRITISH COLONIES, POSSESSIONS, AND PROTECTORATES. Part XXXI. 1906. [Cd. 4385.] Price 6s. 2d.

This return, which is prepared annually in the Commercial, Labour and Statistical Department of the Board of Trade, contains much statistical information in regard to British Colonies, Possessions, and Protectorates supplementary to the figures published in the "Statistical Abstract for the British Empire" and the "Statistical Abstract for the Colonies." The present issue, which relates to the year 1906, contains statistics of the population, foreign trade, shipping, finances, agriculture, and other industries of the various Colonies, &c. Among statements appearing for the first time may be mentioned those respecting the number and tonnage of vessels engaged in the foreign and inter-state trade of the Australian Commonwealth during 1906, the number and tonnage of vessels built in the Commonwealth in 1906, the value of Australian inter-state trade in 1904, 1905, and 1906, mineral statistics of the Orange River Colony for each of the years ended 30th June, 1904 to 1906, shipping statistics of the Nyasaland Protectorate for the year ended 31st March, 1907, statistics respecting industrial establishments in Canada, &c., &c.

DIE VERWERTUNG DES KALIS IN INDUSTRIE UND LANDWIRTSCHAFT. Eine wirtschaftliche Studie in vier Abschnitten. Von Dr. PAUL KRISCHE, Göttingen und Stassfurt. Wilhelm Knapp's Verlag, Halle a. S. 1908. Price M.5.70.

8vo volume, containing 181 pages of subject matter with 16 illustrations, and a chart. The subdivisions of the text are as follows:—I. The most important sources of potash. II. Development of the potash industry. III. The industrial valuation of potash. IV. The manual valuation of potash. V. The prospects of the potash industry.

LABORATORIUMSBUCH FÜR TINKTORIAL-CHEMIKER, KOLORISTEN, INGENIEURE, UND TECHNISCHE REISENDE, IN FÄRBEREIE, DRUCKEREIE, FARBEN-, LACK- UND PAPIERFABRIKEN. Von Dr. FRANZ ERBAN. Wilhelm Knapp's Verlag, Halle a. S. 1908. Price M.5.20.

This volume forms one of the publisher's "*Laboratoriumsbücher für die chemische und verwandte Industrie, Bd. IV.*" It contains 109 pages of subject matter, with 21 illustrations. There is no alphabetical index, but a very full and complete table of contents. The subject matter is classified as follows:—I. The laboratories in dye- and print-works. II. The dyeing laboratories and experimental dye-houses of dye-works. III. Concerning the advancement of dye-works chemists and colourists, and their prospects.

FIRE TESTS WITH FIRE EXTINGUISHERS. "Red Books" of the British Fire Prevention Committee. No. 128. ["Red Book" No. 128.] Edited by the Committee. Published at the offices of the Committee, 1, Waterloo Place, Pall Mall, London. 1908. Price 2s. 6d.

Svo pamphlet in stout cardboard cover of red colour, containing 16 pages of subject matter. The objects of the tests were to ascertain the effect of the application of water in small vessels, such as buckets, etc., upon various burning materials both in a room and in the open. There were in this case 12 tests. Illustrations are given. Particulars are given of these experimental tests. They were made in connection with the employment of buckets of water, hand pumps, etc., as in common use.

["Red Book" No. 133.] Price 2s. 6d.

Svo pamphlet similar to the last, and containing 24 pages of subject matter and 11 illustrations. The object of the tests in this case was to ascertain the effect of the application of asbestos cloths, sand, and steam upon petrol and various burning materials, though principally upon burning petrol, and more particularly under conditions met with in processes employed on the premises of dyers and cleaners.

ELEKTROLYTISCHE ZÄHLER. [Monographien über angewandte Elektrochemie Bd. XXXI.] Von Dr. KONRAD NORDEN. Wilhelm Knapp's Verlag, Halle a. S. 1908. Price M.9.00.

Svo volume, containing 161 pages of subject matter with 150 illustrations, and an alphabetical index of names, followed by an index of patents, German, English, and American. The subject is arranged under the following classification:—PART I. A. General facts on galvanometers, specially ammeters. B. Essential practical conditions. C. The electrochemical conditions. PART II. (i), Copper voltameter, (ii.), Zinc voltameter, (iii.), Silver voltameter, (iv.), Mercury voltameter, (v.), Water voltameter. PART III. (i.), Precipitate voltameters, (ii.), Mercury electrometer, (iii.), Hydrogen electrometer.

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

55. Iron. Furnaces and kilns. Jan. 1.
146. Ruddle. Collecting, handling, and storing liquors, etc., by means of organic absorbents, for the subsequent recovery of nitrogenous and other compounds therefrom. Jan. 2.

370. Peake. Thermo-electric pyrometers. Jan. 7.
397. Schmatolla. Furnaces, kilns, &c. [Addition to No. 1168 of 1908.] Jan. 7.
654. Cloake. Heating apparatus. Jan. 11.
779. Brücke. Apparatus for distilling, evaporating, heating, or cooling liquids. Jan. 12.
828. Jones. Perforated top cone kiln thermometer. Jan. 13.

916. De Brumo-Austin. Automatic apparatus for dissolving. [Addition to No. 6842 of 1907.] Jan. 14.

1151. Thompson (Badische Maschinenfabr. und Eisen-giesserei vorm. Schell und Neff). Separating substances of different specific gravities. * Jan. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

26,584 (1907). Pampé. Notched columns for distilling and rectifying purposes. Jan. 13.

26,821 (1907). Elmore and Elmore. Apparatus for separating sub-divided solids from a liquid, especially for thickening ore pulp, &c. Jan. 13.

20,686 (1908). Bowmer. Gas producers. Jan. 13.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

71. Davies and Vivian. Separation of certain components of certain liquid hydrocarbons. Jan. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

1921 (1908). Backeland. Insoluble condensation products of phenol and formaldehyde. Jan. 13.

13,675 (1908). Noad and Townsend. Production of volatile spirit from hydrocarbon oils, &c. Jan. 13.

IV.—COLOURING MATTERS AND DYE-STUFFS.

APPLICATIONS.

111. Perkin. Manufacture of indigo from the indigo plant. Jan. 2.

339. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the anthracene series. Jan. 6.

657. Newton (Bayer und Co.). Manufacture of azo dyestuffs. Jan. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

90 (1908). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters containing sulphur. Jan. 13.

5484 (1908). Newton (Bayer und Co.). Manufacture of trisazo dyestuffs. Jan. 20.

8530 (1908). Imray (Soc. Chem. Ind. in Basle). Manufacture of halogenised vat dyestuffs. Jan. 20.

11,878 (1908). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters suitable for use in the form of their lakes. Jan. 20.

26,714 (1908). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matter suitable for use as a pigment or lake. Jan. 13.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

169. Baumann and Diesser. Process for obtaining silk fibroin, albumen, etc. [Ger. Appl. Sept. 15, 1908. Addition to No. 25,522 of 1908.]* Jan. 4.

270. Cassella and Co. Dyeing union fabrics. [Ger. Appl., Jan. 6, 1908.]* Jan. 5.

271. McNaught. Machinery for scouring and washing wool and other fibrous materials. Jan. 5.

625. Garsedden and Ingram. Automatic skein or hank dyeing machine. Jan. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

27,006 (1907). Scott. Degreasing and cleaning fabrics, yarns, etc. Jan. 13.

858 (1908). Dreaper. Manufacture of threads or filaments from cellulose. Jan. 20.

6979 (1908). Calico Printers' Assoc. and Schofield. Printing textile fabrics. Jan. 20.

8142 (1908). Newton (Bayer and Co.). Printing with the aid of sulphide dyestuffs. Jan. 13.

16,659 (1908). Chaumat. Indigo dyeing. Jan. 13.

19,310 (1908). Imray (Soc. Chem. Ind. in Basle). Producing in printing violet to lilac tints fast to washing and light. Jan. 20.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

52. Firman and Cocksedge. Apparatus for making sulphur and similar acids. Jan. 1.

146. Ruddle. *See under* 1.

351. Weyer. Production of nitric acid.* Jan. 6.

491. Poulson. Manufacture and utilisation of gelatinous silica. Jan. 8.

562. Leese. *See under* IX.

596. Williams. Extraction of sulphur from spent oxide, &c.* Jan. 9.

612. Leese. Preparation of magnesite in impalpable powder, and of calcined magnesite therefrom.* Jan. 11.

711. Herrmann and Co. Packing peroxides of alkalis. [Swiss Appl., Jan. 13, 1908.]* Jan. 11.

794. Bailey and Stevenson. Production of borax from native boron compounds.* Jan. 12.

1148. British Cellulose Synd., and Mertz. Production of a solution of ammoniacal cupric oxide.* Jan. 16.

1150. Gruner. Production of a sodium peroxide compound for washing and bleaching. [Ger. Appl., Feb. 28, 1908.]* Jan. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

22,434 (1907). Tucker. Manufacture of massive boron carbide. Jan. 20.

651 (1908). Naumann. Production of sal-ammoniac by decomposing common salt with ammonium sulphate. Jan. 13.

Birmingham Section.

Meeting held at Birmingham on Thursday, December 10th, 1908.

MR. HENRY SILVESTER, B.Sc., F.I.C., IN THE CHAIR.

APPARATUS USED IN RAPID METHODS OF ELECTRO-ANALYSIS. ANALYSIS OF BRASS.

BY T. SLATER PRICE, D.Sc., Ph.D., F.I.C., AND
T. C. HUMPHREYS.

The history of rotating electrodes in electrolytic analysis has lately been a subject of much discussion, various investigators claiming to have been the first to use them. As the result of this discussion we may take it that the idea of the use of a rotating electrode occurred to a number of different investigators at much about the same time; the results of their investigations were first published some time during the year 1903. (Goode and Medway, *Amer. J. Sci.*, 1903, 15, 320; this *J.*, 1903, 823; Exner, *J. Amer. Chem. Soc.*, 1903, 25, 896; this *J.*, 1903, 1150; F. M. Perkin, Paper read before the Faraday Society, June 30, 1903; *Electrochem. and Metall.*, 1903, 3, 22; this *J.*, 1903, 1064.) It should, however, be mentioned that Klobukow (*J. pr. Chem.*, 1886, 33, 473) was probably the first to point out the advantage of stirring the electrolyte during the passage of the current; after first trying rotating the cathode and then the anode, and finally agitating the electrolyte while the electrodes were kept stationary, he came to the conclusion that it was best to rotate the anode. He did not publish any results, however, and it was left for the above-mentioned investigators to be the first in the field. In 1904 further results were published by students working in Classen's laboratory at Aachen (Amberg, *Z. Elektrochem.*, 1904, 10, 385 and 853; Fischer and Boddaert, *ibid.*, 1904, 10, 945), and since that time there have been numerous publications dealing with the same subject, a great number of the investigations having been carried out by students working under E. F. Smith of the University of Pennsylvania. Probably the most important work in this connection which has been published lately is that which has been done by Sand (*Trans. Chem. Soc.*, 1907, 91, 373; 1908, 93, 1572; this *J.*, 1907, 490; 1908, 963).

The apparatus which is used by the different investigators varies considerably; it may be divided into the following classes according to whether the anode, cathode, or electrolyte only is kept in rapid motion:—

1. *Rotating anode*.—(a). Dish cathode and wire or disc anode. (b). Cylindrical cathode and anode of fine gauze. (c). Mercury cathode and wire anode.

2. *Rotating cathode*.—(a). Cylindrical cathode made of platinum gauze. (b). Cathode made of a platinum crucible. (c). Spiral wire cathode.

3. *Electrodes stationary, electrolyte stirred*.—(a). Electrolyte stirred by mechanical means. (b). Electrolyte stirred by electro-magnetic force.

The above classification is not supposed to be complete, nor is every type of apparatus dealt with; it is only intended as a rough guide. We will deal shortly with each of these classes.

1. ROTATING ANODE.

(a). *Dish cathode and wire or disc anode*.—Since one of the commonest forms of apparatus used with stationary electrodes consisted of a dish cathode and a wire anode, it was only natural that attempts should be made to utilise the same apparatus for the purpose of rapid electro-

FIG. 1.

analysis. The diagram (Fig. 1) illustrates such an apparatus as used to a great extent in the laboratories of Smith and Classen.

FIG. 2.

Instead of the wire anode a perforated disc anode may be used. This apparatus has been found to give very good results, although our limited experience of it has not been very satisfactory, except in so far as the determination of copper is concerned. It suffers, theoretically, from the disadvantage that the distribution of the current between the anode and the cathode is very uneven, and this may have led Miss Langness (working under Prof. Smith) to devise the anode shown in Fig. 2 (*J. Amer. Chem. Soc.*, 1907, 29, 460; this *J.*, 1907, 644). Its shape conforms to that of the dish cathode, and in its sides are ten slits perpendicular to the edge. Free circulation of the electrolyte is ensured by these openings, and through a circular opening in the bottom of the dish. The anode is so adjusted that it is equidistant from the sides of the cathode, and the electrolyte, during the rotation of the anode, is all contained within the space bounded by the cathode and the outer surface of the anode; there is none within the inner dish. The volume of electrolyte does not exceed 60 c.c., and when the electrodes are properly adjusted there is no splashing and no loss of electrolyte. With this apparatus 0.4884 gm. of copper could be deposited (quantitatively) in 3 minutes, using 10–15 amps. and 8 volts.

(b). *Cylindrical cathode and anode of wire gauze*.—The best apparatus of this kind is that due to Sand. The

FIG. 3a. FIG. 3b. FIG. 3c.

FIG. 3a.—Outer electrode. FIG. 3b.—Glass tube. FIG. 3c.—Inner electrode with part of gauze removed.

FIG. 3.

complete apparatus, as well as the parts, is shown in Figs. 3 and 4. The outer electrode (1a) completely

FIG. 4.—A, Clamp to grip outer electrode. B, Chuck to grip inner electrode. C, Glass tube rotating in glass tube D. E, Oil trap on C. F, Thick rubber tube. G, Amalgamated copper wire dipping into mercury contained in C and F. H, Cord made of violin string. I, Pulley made of rubber tube.

FIG. 4.

surrounds the inner rotating electrode (1c) on all sides except the bottom, the two being kept in position relatively to each other by means of the glass tube (1b) which is slipped through the collar, A, and the ring, B, of the outer electrode. It is gripped firmly by the former, but passes loosely through the latter. The hollow platinum-iridium stem, A, of the inner electrode is passed through the glass tube, in which it rotates freely. The inner electrode is designed to produce a maximum amount of rotation of the liquid, and for this purpose has a vertical partition, P. The gauze of the outer electrode almost completely stops the rotation of the liquid. While the electrolyte is therefore rapidly ejected from the centre of the inner electrode by centrifugal force it is continually replaced by liquid drawn in from the top and bottom. As the outer electrode surrounds the inner completely, the lines of flow of the current are contained between the two, and even when strong currents are employed the potential of the electrolyte anywhere outside the outer electrode is practically the same as that of the layer of liquid in immediate contact with it. The space between the two electrodes is about 3 mm. Fig. 4 illustrates the manner in which the electrical connections are made, that to the anode, which is fastened in the chuck, B, being made by means of mercury contained in the glass and rubber tubes, C and F. For details as to dimensions, etc., reference must be made to the original paper (*loc. cit.*). This apparatus has been designed with a view to carrying out separations by the method of graded potential, and it has shown itself eminently adapted for that purpose, although it seems to the authors to be unnecessarily complicated. In his last paper (*Trans. Chem. Soc.*, 1908, 93, 1572; this J., 1908, 963) Sand gives a description of the quantitative estimation and separation of antimony and tin. The method used for the estimation of antimony is a very great step forward, since in all previous methods, with perhaps one exception, (Scheen, *Z. Elektrochem.*, 1908, 14, 257; this J., 1908, 575) the deposited metal has always contained small quantities of occluded electrolyte.

(c) *Mercury cathode and wire anode.*—Although many early investigators had endeavoured to make use of a mercury cathode, the first really successful apparatus was devised by Howard, working in Smith's laboratory. A diagram of the apparatus is shown in Fig. 5. It consists of a small tube or beaker of about 50 c.c. capacity, near or in the bottom of which there is introduced a thin platinum wire, by means of which the current is supplied to the mercury cathode. The anode may be either a per-

FIG. 5.

forated platinum disc or a spiral of stout platinum wire. Since the amount of platinum is a minimum the apparatus is comparatively cheap, and it also possesses the advantage that it can be readily made with the materials usually at hand in a chemical laboratory. Reference to the literature (*J. Amer. Chem. Soc.*, 1905, 27, 1255 and succeeding volumes) will show that analyses can be conducted very quickly with this apparatus; e.g., 0.3945 gm. of copper was deposited in 4 minutes, using a current of 3.5 amps. at 8.5 volts. It possesses the disadvantage that very great care is necessary in washing the amalgam with water, alcohol, and ether, preparatory to drying, or else small quantities of mercury may be detached and lost. In the case of zinc determinations, as has been shown by one of us (*Price, Trans. Faraday Soc.*, 1907, 3, 88; this J., 1907, 345), there is always a small loss of zinc and mercury during the washing, so that the results are low. This has recently been confirmed by Porter and Frary in a paper read at the 14th General Meeting of the American Electrochemical Society, Oct. 30-31, 1908.

2. ROTATING CATHODE.

(a) *Cylindrical cathode made of gauze.*—One of the best of this type of apparatus is that due to Perkin, and first described by him in a paper read before the Faraday Society (*loc. cit.*). As will be seen from Fig. 6, the anode is in the form of a double circle of stout platinum wire, and has four little baffle plates placed at intervals around it, to prevent the liquid from rotating with the cathode. If the apparatus is to be used for the determination of lead as peroxide the rotating electrode becomes the anode. While dealing with this apparatus it may be as well to once more call attention to the use of a bicycle hub for rotating the electrode. This arrangement, which is a very cheap one, was first described by Price and Judge (*Trans. Faraday Soc.*, 1906, 2, 85), the idea of using a hub for such purposes being suggested to us by Mr. Heathcote, and since that time it has been in continual use and has been found to be perfectly satisfactory. An improved form of hub is shown in Fig. 6A. Instead of the current being conducted to the spindle in the manner shown in Fig. 6, an ordinary terminal is screwed into the barrel of the hub at the oil-hole; the balls are lubricated with a mixture of graphite and oil. If it is desired to obviate the drop in potential across the balls of the hub, so that the apparatus can be used for electrolyses with graded potential, the current is led directly to the spindle by the arrangement shown (in section) at the top of the diagram. A small hole is drilled in the end of the spindle and a platinum wire soldered into it. A small cup is formed where the grooved pulley screws on to the spindle, and into this is fitted, by means of india rubber tubing, or better, by means of red lead or cement, a glass cup. The platinum wire projects up into this glass cup, which is filled with mercury to an appropriate height; the leading wire from the current terminals then dips into the mercury. The electrode is held in position by means of a small chuck, which is screwed into the lower end of the spindle. Another modification

FIG. 6.

Another modification

FIG. 6A.

which was introduced at the same time was the replacement of the beaker which is generally used to hold the electrolyte by a tap funnel. This is of great advantage for washing the deposited metal without stopping the current or removing the electrode from position, and is infinitely to be preferred to the usual method of siphoning off the electrolyte while at the same time distilled water is run into the beaker containing the electrodes. Care should be taken that the tap of the funnel fits tightly and does not become loose during the electrolysis. Of course, the funnel cannot be used with stationary electrodes or electrolyte, as some of the solution would remain in the neck of the funnel and escape electrolysis.

FIG. 7.

(b) *Cathode made of a platinum crucible.*

—This was the apparatus used by Gooch and Medway (Amer. J. Sci., 1903, 15, 320; this J., 1903, 823), and is sufficiently explained by Fig. 7. To secure electrical connection between the crucible and the shaft of the motor a narrow strip of sheet platinum is soldered to the shaft and then bent upwards along the sides of the stopper, thus putting the shaft in contact with the

inside of the crucible when the latter is pressed over the stopper.

(c) *Spiral wire cathode.*—This apparatus was described by Perkin (Trans. Faraday Soc., 1906, 2, 91; this J., 1906, 609), and is mentioned here because it is simple to make and not very expensive in platinum. The cathode consists simply of a spiral of platinum wire, the total active area of which is about 23 sq. cm.

3. ELECTRODES STATIONARY. ELECTROLYTE STIRRED.

FIG. 8.

(a) *Electrolyte stirred by mechanical means.*—A very convenient apparatus of this kind, and one which can be used for separations by graded potential, is due to A. Fischer (Z. Elektrochem., 1907, 13, 469). Fig. 8. The two electrodes are concentric cylinders of wire gauze; they are fixed in position and kept from touching each other by three glass rods which are fastened to the inner electrode (one only is shown in the diagram). The electrolyte is stirred by a glass stirrer of appropriate shape.

(b) *Electrolyte stirred by electro-magnetic means.*—A most ingenious apparatus of this kind is due to Frary

(Z. Elektrochem., 1907, 13, 308; J. Amer. Chem. Soc., 1907, 29, 1592; this J., 1907, 875), and is shown in Fig. 9. No motor is necessary, and the electrodes are stationary. The electrolyte is rapidly rotated in the magnetic field due to the solenoid which surrounds the beaker. When the current flows through the solenoid a uniform magnetic

FIG. 9.

field is formed in the beaker, the lines of force being vertical. If, now, the current passes from one electrode to the other through the electrolyte, the lines of current in the latter are radial and horizontal. Every infinitesimal strip of electrolyte between the electrodes acts as if it were a wire carrying a current. The current direction is in every case perpendicular to the magnetic lines of force, which, therefore, push the electrolyte in a direction perpendicular to their direction and to that of the current. In other words, every particle of the electrolyte between the electrodes is acted on by a horizontal force which pushes it in a direction perpendicular to a radius of the cylinder drawn through it. The whole electrolyte therefore revolves about the anode as a cylinder about its axis. The electrolytic cell and the solenoid may be connected in series or worked by separate circuits. The heat developed in the solenoid may be used for warming the electrolyte, but if this is not desired the beaker may be surrounded by a spiral or lead pipe through which cold water flows. Very satisfactory results were obtained with this apparatus in the electrolytic determination of copper and zinc.

The above sketch of the various apparatus is not by any means complete; it has been given in order to illustrate various kinds of apparatus. For other apparatus, and especially that dealing with the electrolytic determination of anions (Hildebrand, J. Amer. Chem. Soc., 1907, 29, 447; this J., 1907, 644) reference must be made to the literature. Attention may be called to articles which describe sets of apparatus for rapid electro-analysis, which have been installed on a large scale either in work or in University laboratories (Sheppard, J. of Phys. Chem., 1903, 7, 568; Fairlie and Bone, Electrochem. and Metall. Ind., 1908, 6, 10; Classen, Z. Elektrochem., 1907, 13, 181).

As has already been indicated by a number of the examples given, the advantage of rotating the electrode, or, what comes to the same thing, of efficiently stirring the electrolyte, lies in the fact that the time necessary for the quantitative deposition of a metal is considerably shortened, because of the high currents which can be used. If one attempts to use high currents with stationary electrodes the usual result is that a spongy deposit is obtained. The explanation of this has been fully discussed by Dannel (Z. Elektrochem., 1903, 9, 763), Sand (Z. Elektrochem., 1904, 10, 452) and Amberg (Z. Elektrochem., 1904, 10, 385 and 853) so that we do not intend to do more than just touch on the explanation, taking as an example the electrolysis of an acid solution of copper sulphate. If too high a current is used with stationary electrodes the solution in the immediate neighbourhood of the cathode rapidly becomes depleted of copper, or rather of copper ions, since ordinary diffusion together with the migration of the ions, does not replace them as quickly as they are deposited. The result of this is that the potential of the cathode rises until it attains such a value that hydrogen can be deposited, together with any copper which may be supplied to the electrode by diffusion, or by convection currents caused by the evolved gas stirring the electrolyte.

When, however, the electrolyte is rapidly stirred, the solution in the immediate neighbourhood of the cathode is kept of the same concentration as the main bulk of the solution without any difficulty, with the result that there are always plenty of copper ions to carry the larger current used. Of course, as the deposition of copper takes place, the potential of the cathode gradually increases, and if the current is kept constant the potential will finally reach such a value that towards the end of the electrolysis hydrogen will be evolved, even with rotating electrodes. In the case of copper this evolution of hydrogen towards the end of the electrolysis does not generally much matter, but in other cases it may be advisable to continually lower the current strength as the electrolysis proceeds, and have it as nearly proportional as possible to the diminishing average concentration. This is where the advantage of the method of "graded potential" comes in, since the potential at the cathode is then kept practically constant, and the strength of the current passing will automatically diminish as the concentration of the ions which can be deposited at that potential decreases. The exact reason as to why the simultaneous deposition of hydrogen and a metal should cause the latter to be spongy in character is a matter which still remains to be definitely decided. According to some it is this simultaneous deposition which is the real cause, the hydrogen evolved preventing the deposited metal from cohering together. Others believe that an unstable hydride of the metal is first deposited, and this on decomposition leaves the metal in a spongy form. Still others give the explanation that under certain circumstances, owing to the rapid evolution of hydrogen, the solution in the immediate neighbourhood of the cathode becomes largely depleted of H-ions, thus becoming alkaline; some insoluble hydroxide of the metal is thus formed, and adheres to the cathode, preventing the metal which is further deposited from becoming coherent. It is possible that different explanations will hold for different cases.

The question may be asked: which is better, a rotating cathode or a rotating anode (assuming that a metal is being deposited, and not a peroxide)? As far as one can judge from the results which have already been published, the answer seems to be that in most cases, except as a matter of convenience, neither one is to be preferred to the other. We think it may be stated, however, that the dish cathode and wire anode is the apparatus which is least satisfactory. The way in which rapid stirring of the electrolyte acts has already been referred to, but if the question is considered more in detail, one will find that the rate of electrolysis is ultimately dependent on the rate at which diffusion takes place through a surface layer in contact with the cathode. The more efficient the stirring, the thinner is this surface layer, and the quicker the diffusion through it, and therefore the more rapid the electrolysis. Now the dish cathode and wire anode is not as mechanically efficient as the other forms of apparatus described, and it moreover suffers from the drawback, already pointed out, that the distribution of the current is very uneven. One advantage which, however, has been claimed for it, is that the rotating liquid exerts a pressure on the deposited metal (Amberg, *Z. Elektrochem.*, 1904, 10, 855) and thus makes it more adherent. This may be so, but it seems to us to be somewhat doubtful.

No one will question that, as far as the saving in time is concerned, the methods of rapid electro-analysis are a great improvement on the older ones. This does not prove, however, that it is always an advantage to use them. Since the apparatus used is more complicated than that necessary for stationary electrodes, it requires almost continuous supervision during the electrolysis—especially is this the case when the method of graded potential is used—so that no other work can be done conveniently at the same time. This does not hold when stationary electrodes are used, and electrolyses with the latter also possess the great advantage that they may be run over night, and that the apparatus required is not so costly. As to which method is used depends to a large extent on the convenience of the analyst and on the time within which the analytical results must be ready. In some cases there are no satisfactory rapid methods of analysis, but as time goes on there is no doubt that all electrolyses which can be carried out with stationary

electrodes will also be capable of being accurately done by quick methods.

In most cases work which has been carried out with one kind of apparatus may be successfully repeated with another. This is not always true, however, and a typical case seems to be that of zinc. If one can trust all the published results, methods which can be successfully employed for zinc with a dish cathode and a rotating anode cannot be used with a rotating gauze cathode. Even when using the same apparatus for a series of zinc determinations it sometimes happens that a number of bad results will be obtained, in spite of the fact that the method has hitherto been deemed satisfactory, and for which there does not seem to be any apparent reason (*Cf.* Price, *Trans. Faraday Soc.*, 1907, 3, 88). In some cases it seems as if the original observer has simply made a number of different determinations, taking the same volume of solution containing the salt in each case, and if he found that the same weight of metal was deposited in each experiment, he came to the conclusion that the method was satisfactory and published the results, without satisfying himself that *all* the metal had been deposited. This seems to have been the case in the experiments of Exner (*J. Amer. Chem. Soc.*, 1903, 25, 896), Ingham (*Ibid.*, 1904, 26, 1269), Langness (*Ibid.*, 1907, 29, 459), and Medway (*Amer. J. Sci.*, 1906, 18, 810), on the electro-analysis of zinc, as was first pointed out by Frary (*J. Amer. Chem. Soc.*, 1907, 29, 1596). One of the present authors can confirm this, as in his experiments on zinc (Price, *Trans. Faraday Soc.*, 1907, 3, 88), he endeavoured to repeat some of Exner's and Ingham's work, and could not obtain satisfactory results; at the time this was ascribed to want of practice with the apparatus, and therefore no reference was made to it in the above-mentioned paper.

In the experiments on the electro-analysis of brass, which are to be described later, we have not used the method of graded potential, but the one ordinarily used in most of the standard separations; these may generally be classed as constant current separations, even though the current may not be kept absolutely constant (*Cf.* Bancroft, *International Congress*, 1903, 4, 703). In order to prevent the second metal precipitating as soon as the first is all down, it is essential that hydrogen shall be set free by the current instead of the second metal, i.e., that the deposition potential for hydrogen shall lie below the deposition potential of the second metal. Most analyses and separations were originally made without a voltmeter being used, and consequently the constant current separations were first worked out.

In all work where a constant current method is used it is customary to give the voltage across the electrodes. This is sometimes misleading, since the voltage across the electrodes which is necessary to obtain a given current not only depends on the potentials at the electrodes, but also on the resistance of the electrolyte between them; the latter is a very variable quantity, depending on the temperature and concentration of the electrolyte and on the distance apart of the electrodes. Thus, although one may use the same current with two different kinds of apparatus, the e.m.f. necessary to obtain this current may vary somewhat in the two cases.

We have not used the method of graded potential because a number of the results have been obtained in the works where one of us is employed, and the necessary apparatus was not available there. The apparatus used is that described by Price and Judge (*loc. cit.*), the cathode consisting of a cylinder of wire gauze (4 meshes to the sq. mm.), 40 mm. long and 20 mm. in diameter. This apparatus can be conveniently used for certain potential separations, without it being necessary to use an auxiliary electrode, electrometer, etc. For example, the separation of copper and silver can be readily carried out as follows:—0.5 grm. of the alloy of copper and silver is dissolved in 4 c.c. of concentrated nitric acid, 25 grms. of ammonium acetate added, and the solution diluted to 50—75 c.c. By means of a ring burner the contents of the funnel are heated to boiling, and then 1.1 volts are put across the electrodes, a current of 1—1.5 mps. being thus obtained (*Cf.* Sand, *loc. cit.*). At this potential only silver is deposited, and if care is taken not to let the potential

rise above 1.1 volts, a complete separation of silver from copper is obtained. The deposition of silver is complete when the current has fallen to 0.1 amp. Time: 10–20 minutes.

Analysis of brass.

In dealing with the analysis of brass by rapid electrochemical methods we shall only consider the estimation of the copper and the zinc. The other metals which are usually present in very small amounts, *e.g.*, lead, iron, tin, etc., are perhaps most conveniently estimated by the ordinary chemical methods.

Estimation of copper.—The instructions with respect to the amount of nitric acid which may or may not be used in the estimation of copper in alloys are usually very indefinite, and as a consequence of this we soon met with difficulties in our experiments. We often found that at the commencement of the electrolysis a good deposit of copper was obtained, but that no matter how long the current was passed we could not get all the copper out of the solution. In some cases the solution remained strongly coloured all the time, whereas in others, after practically all the copper had been deposited—judging by the colour of the solution—on continuing to pass the current, the copper again began to dissolve. These results were due to the solvent action of the nitric acid on the deposited copper, the probable cause of the re-solution which took place in some cases being the increased solvent action brought about by the rise in temperature of the electrolyte due to the passage of the current. In order to investigate the influence of nitric acid with the particular apparatus used by us, we have carried out a large number of experiments, some of the results of which we now put forward for your consideration. Since our experiments were completed, now some little time ago, Withrow (*J. Amer. Chem. Soc.*, 1908, **30**, 381) and Fairlie and Bone (*Electrochem. and Metall. Ind.*, 1908, **6**, 58; this *J.*, 1908, 954) have published the results of somewhat similar investigations, but using different apparatus.

For the first series of experiments a solution of copper nitrate was used. This was made by dissolving a known weight of pure electrolytic copper in pure nitric acid and evaporating the solution down to dryness several times on the water bath. The residue so obtained was dissolved in water and a small quantity of nitric acid, just enough of the latter being added to dissolve the basic nitrate formed during the evaporation. The solution was made up to a definite volume, and aliquot parts taken for analysis. Some of the results are given in the following table. In each case a current of 3 amperes was used, and the voltage was also 3, except in the first experiment, when it was 4–5. All the determinations were carried out at ordinary temperature, except in the cases where they are marked with an asterisk (*), when a hot (practically boiling) solution was used. In each case the volume of the solution was about 75 c.c. and the number of rotations per minute of the cathode was 600–700. The method of working the apparatus has already been described by Price and Judge (*loc. cit.*).

† 1 c.c. of the arsenic acid solution used contained 0.00052 gm. of arsenic.

Each of the above results has been repeated several times, but all the experiments are not given in order to save space. It will be noticed that in all the experiments where nitric acid is the only additional electrolyte the copper is never completely deposited, but that when 1 c.c. of concentrated sulphuric acid or 1 gm. of zinc sulphate is added a quantitative result is obtained, the electrolysis taking place at ordinary temperatures. At high temperatures it is necessary to use 2 grms. of zinc sulphate. In all cases where iron is present the results are low; this is due to the fact that oxidation of the ferrous salt takes place at the anode, and the ferric salt so formed dissolves some of the deposited copper. This action of iron salts can be prevented by reducing the area of the anode very considerably, or by using a diaphragm round the anode (*Cf. Sand, Trans. Chem. Soc.*, 1908, **93**, 1572). The amount of iron which is generally present in brass is, however, not enough to interfere with the ordinary electrolytic methods, as will be seen later. It is interesting to observe that quantitative results were obtained in the presence of considerable quantities of arsenic, which was present in the pentavalent condition*; moreover the deposit was always a very good colour.

In the next series of experiments a solution of pure copper sulphate was used, with the following results:—

Copper used.	Copper found.	Nitric acid used.	Sulphuric acid used.	Time.	Remarks.
grms. 0.5075	grms. 0.5078	c.c. 4	c.c. —	mins. 35	
"	0.5075	4	—	35	
"	0.5070	4	—	30	
"	0.5076	—	2	30	Deposit was bright for 10 mins., and then went dull.
"	0.5072	—	2	20	Deposit dark red.
"	0.5075	—	5	30	
"	0.5095	—	2	20	Plus 10 c.c. As. solution. Deposit black.

The above results show that, in the presence of sulphuric acid and nitric acid in the proportions given, the copper is quantitatively deposited. Even when free sulphuric acid is alone present correct results are obtained, although the deposits are of a dull or dark red colour; this is due to the deposit becoming slightly powdery towards the end of the electrolysis, although not to such an extent that some of it is lost in the washing. (*Cf. Sand, loc. cit.*) If the solutions contain a large amount of free sulphuric acid, or if the current (3 amps.) is passed too long, the deposit is liable to become black, owing to some of the sulphuric acid being reduced to sulphuretted hydrogen, which gives rise to the formation of copper sulphide. This can be obviated by cutting down the current as the electrolysis proceeds (*Cf. pp. 120 and 122*). Unless free nitric acid is present the addition of arsenic causes the deposit to become black, and the result is high.

In all the experiments detailed above, the times given do not refer to the minimum times necessary for the deposition of the copper. An excess of current has always been used, in order to see if the results were thereby affected, since in actual practice one cannot always stop the electrolysis immediately the copper is all deposited.

As the result of our experiments we have come to the conclusion that copper cannot be quantitatively deposited with certainty from a solution in which nitric acid is the only acid present. This statement refers to the use of rotating electrodes; with stationary electrodes (and electrolytes) all the copper can often be so deposited, although the time necessary is very prolonged; even in the latter case, however, the result is never certain, and it is better to have sulphuric acid present.

Estimation of copper and zinc in brass.—Two methods have been employed for the estimation of copper and zinc in brass.

1.—About 0.7 gm. of brass is dissolved in 4 c.c. of concentrated nitric acid and a little water; the solution is

* *Cf. Ashbrook, Jour. Amer. Chem. Soc.*, 1904, **26**, 1283.

then transferred* to the tap funnel of the apparatus, made up to 75–100 c.c., 1 c.c. of strong sulphuric acid added, and electrolysed, using 3 amperes and 3 volts (approx.). The copper is all deposited in 20–30 minutes, and the deposit is treated in the usual manner. The solution and washings are run off into a porcelain dish and evaporated down on the water bath, completing the evaporation on a sand bath until sulphuric acid fumes appear, in order to drive off all the nitric acid. The residue is dissolved in a few c.c. of water (with a little sulphuric acid if necessary) and a solution of sodium hydroxide (250 grms. per litre) carefully added till the zinc begins to precipitate out as hydroxide (about 6–8 c.c. of the alkali are necessary). Enough ammonia is then added to dissolve the precipitate, the solution is gently warmed† till the precipitate of ferric hydrate separates, and filtered through a small funnel and filter paper in order to remove the iron. The precipitate of ferric hydrate is washed with hot water and ammonia (about 6–8 c.c. of strong ammonia are necessary in the two operations). Glacial acetic acid is then added until the solution is just acid, and the latter is then electrolysed with 2 amps. and 4–4.5 volts, using the cathode on which the copper has been previously deposited. Time necessary, about 20 mins. The deposits are in all cases very good, and the results accurate. The ammonium acetate in the presence of sodium sulphate does not affect the deposit of zinc, although ammonium acetate alone as additional electrolyte gives high results (*Cf.* Price, *Trans. Faraday Soc.*, 1907, 3, 88). Several of the ferric hydroxide precipitates have been tested for zinc by dissolving them in acid, reprecipitating, and testing the filtrate with ferrocyanide, but in no case was any found.

The statement is often made, that small amounts of

in a beaker on a sand bath till it becomes syrupy; it is allowed to cool somewhat, 3 c.c. of concentrated sulphuric acid added, and again heated till fumes of sulphuric acid appear. This method obviates bumping, and is quite satisfactory. After taking up again with water, keeping the bulk down as much as possible, any lead sulphate is filtered off, the filtrate being run into the electrolysing funnel, which should be slightly larger than the one generally used (capacity 140 c.c.). The volume of the solution so obtained is about 75 c.c. The copper is then deposited, using a current of 2.5 amps. at 2.5 volts for 5–10 minutes, and then 0.5 amps. (2 volts) for about 20 minutes. A bright deposit of copper is thus obtained. If the current is not reduced as stated, a dark coloured deposit results. The solution is then run off into a small beaker, together with the wash water, very little of which is sufficient if a fine jet is used. The deposit is finally washed with alcohol, dried and weighed. 9 c.c. of strong ammonia are added to the solution, which is then just raised to boiling and filtered back into the electrolysing funnel, the ferric hydrate precipitate being washed with hot water and a little ammonia. The zinc is then deposited on to the weighed copper deposit, using a current of 2 amps. at 3–4 volts. Time necessary, 20–25 mins. The zinc deposit is washed with water and alcohol, and then dried and weighed. It has been shown previously by one of us that good results are obtained for zinc, using an ammonium sulphate plus ammonium hydroxide electrolyte. (*Price, loc. cit.*)

The point should be again emphasised, that in order to obtain satisfactory results, it is necessary to remove the lead, tin and iron, if they would otherwise be present as precipitates suspended in the electrolyte.

Brasses taken.	Copper deposited.	Zinc deposited.	Copper.	Zinc.	Lead.	Iron.	Tin.	Other elements.	Total.

‡ In this case it was necessary to remove the lead as sulphate in order to get a good copper deposit in the solution containing sulphuric acid. If the sulphate of lead is left suspended in the solution, some of it adheres to the copper on the cathode.

suspended precipitate may be left in an electrolyte during electrolysis; this is by no means advisable, however, when rotating electrodes are used.

The above are only a few of the results which have been obtained. The method has now been in daily use for over a year in a works laboratory, and has been found entirely satisfactory for all kinds of brasses.

II.—In the first method some considerable time is taken up in evaporating down the solution after the removal of the copper, in order to get rid of the nitric acid. This does not much matter when a number of analyses are being carried out at the same time, since the evaporations can then be arranged so that there is practically no waiting. The second method about to be given obviates the long evaporation after the copper has been deposited. It is as follows:—0.5–0.75 gm. of brass is dissolved in 2–3 c.c. concentrated nitric acid diluted with about 5 c.c. water. If tin is present the solution is diluted slightly and the oxide filtered off; the filtrate is then evaporated‡ down

* If tin is present, the oxide must be filtered off before proceeding with the electrolysis.

† The solution should not be boiled, otherwise the excess of ammonia is driven off and a hydrate of zinc separates, which is soluble only with difficulty in ammonia.

‡ This evaporation takes very little time, since the bulk of the solution is small.

Brass taken.	Copper deposited.	Zinc deposited.	Copper.	Zinc.	Total.
grms.	grms.	grms.	per cent.	per cent.	

I.—The brass contained 0.03 per cent. of iron. No lead or tin.

0.5032	0.3192	0.1845	63.43	36.67	100.13
0.5053	0.3200	0.1856	63.33	36.73	100.09

DISCUSSION.

The CHAIRMAN said that the electrolytic analysis of copper was one of the most rapid and accurate in metallurgy. As a matter of routine in an ordinary laboratory he thought it was more convenient to allow the determination to go on overnight. The determination was started when one left the laboratory in the evening, and as a rule the copper was ready to weigh on the following morning. What degree of accuracy was obtainable in estimating zinc? It was frequently important to secure the greatest accuracy with reference to the percentage of zinc in high-class spelters. It was usual to make this estimation by difference, after estimating the small amount of impurities present. Would it be possible by the electrolytic method to determine the zinc to 0.03–0.05 per cent.?

Professor T. TURNER said that Dr. Price had confined himself largely to the copper alloys, but, Dr. Sand applied the same method to white metals, and the separation of tin from lead, antimony, and other metals. Then the analyses became more complicated. Regular metallurgical work was distinguished from the work of the professional analytical chemist in that the metallurgist had considerable routine work, and the same kind of materials to test day after day. He thought the old-fashioned method of working a batch of copper analyses by electrolysis, weighing out one batch of say 30 or 40 samples in morning, and weighing in the afternoon, and weighing out a fresh batch in the afternoon to be dealt with on the following day, was simple, and generally speaking left little to be desired. In this way one could do as many assays as a man could weigh in and out.

Mr. E. A. LEWIS did not think the new method of copper estimation would ever oust the old method with stationary electrodes. There were serious objections to the new method; one was the small bulk of solution which was electrolysed, and the other was the smallness of the funnel. And unless the experiments were done by an experienced chemist, they were likely to lead to serious loss. Was the lead peroxide precipitated according to the proper formula; or did it contain less lead than it should do, as in the stationary electrodes? Also was any information available as to the methods for the separation of nickel and zinc? because such methods should be of value in the analyses of German silver.

Mr. H. L. HEATHCOTE said with regard to the interchangeability of a rotating electrode and a rotated electrolyte he gathered from Dr. Price that the effect produced was the same. He (Mr. Heathcote) had not found, in all cases, that the same effect was produced, and exhibited two small pieces of steel tube, which he said had been nickel-plated in an ordinary solution, containing a brightening addition. In the one instance the deposit was almost as brilliant as one that had been mopped; in the other, the solution alone was rotated and the difference was remarkable, the deposit being quite dull. That result was confirmed by other experiments; and showed he thought a radical difference in the effect of rotating the cathode and rotating the electrolyte. As to the cause of sponginess: in the case of nickel his experiments showed that it was due to hydrogen or other gases being projected into the nickel. Microscopic examination showed cavities. He agreed with Dr. Price that the rate of deposition was controlled by the rate of diffusion.

Mr. D. M. LEVY said that during the summer he had an opportunity of seeing Mr. Fairlie's electrolytic apparatus at work at the Tennessee Copper Company's Works in

the U.S.A. They used two methods. In order to see how the matte was running during the day, and where they wanted to return results in about $\frac{1}{2}$ an hour, then they used the rotating cathodes, using about 3 amperes, at five or six volts, and working with hot solution. But for accounting work and works control, where accurate results were essential, they then ran overnight with stationary electrodes. They were quite satisfied with the results of the rapid method using rotating cathodes compared with the chemical methods; although he did not think they were absolutely accurate. They were fortunate at Tennessee in having pure mattes to deal with, containing little but copper, iron, and sulphur. Where there was an electrical installation, or where one could get it easily, and one desired to return results quickly in order to see how the furnace was working, the rapid method with rotating electrodes could not be beaten. In his paper on the so-called "Acetate-copper" Dr. Benedicts (of Upsala) had showed that nodules on the copper surface deposited from acetate solutions contained acetate in some form or other; and that in certain circumstances the sponginess was due to some mechanical fault, through the holding up of portions of the electrolyte in the deposit. The effects of rotation, velocity, temperature and voltage, &c., on the deposit, had been worked out, and the results were very interesting.

Dr. PRICE, in reply, said he made an investigation some time ago (Trans. Faraday Soc. 1907, **3**, 88) on the electrolytic determination of zinc, using a rotating cathode. Instead of starting with zinc, a solution of pure zinc sulphate was used, and his results were accurate to the extent of about four parts in 3000. That did not, of course, quite reach the standards of accuracy desired by the chairman: 99.80 as distinguished from 99.85 per cent. Mr. Humphreys and himself entertained the idea of attacking the estimation of zinc (spelter) as their next problem, in order to see precisely what accuracy could be obtained. It seemed to him, however, that where the difference was exceedingly small such as between 99.80 and 99.85 it was better to estimate the impurities present, and take the zinc by difference. Professor Turner had referred to Sand's method for estimating white metals; but it should be borne in mind, in the separation of antimony and tin, that it was necessary to use the method of graded potential.

Mr. Lewis appeared to doubt whether the method was sufficiently accurate for works. His reply was that those methods were in constant use in more than one large copper works where such analyses were carried out daily. As far as the degree of accuracy was concerned they believed it was quite as great with the quick method as with stationary electrodes. Moreover, anyone acquainted with electrochemical methods of analysis knows that it is advisable to keep the volume of the electrolyte as small as possible. Mr. Levy had pointed out that Messrs. Fairlie and Bone were disinclined to trust the results with the rotating electrodes as much as with the stationary. It might be that their particular apparatus was not altogether suitable. The design did not seem to be altogether satisfactory, since there was not a very even distribution of the current between the anode and cathode. Moreover, he (Dr. Price) was under the impression that the anode, and not the cathode, was rotated. Mr. Humphreys' experience as to reliability was quite conclusive. In reply to Mr. Lewis he (Dr. Price) had always thought that there was always less lead than corresponds the formula PbO_2 owing to the peroxide being deposited in the hydrated condition. This was true whether rotating or stationary electrodes were used. In regard to the separation of nickel and zinc, if there were any nickel in the brass the nickel would deposit with the zinc if their method was used; there was, however, no nickel in the brasses they had analysed. The separation of nickel and zinc could be carried out by the method of graded potential. They had tried one or two experiments by a combination of the ordinary chemical and the electrochemical methods and had been able to analyse German silver quite accurately. Mr. Heathcote's observations confirmed the general experience, in that experiments carried out on a large scale and on a small scale would not always give the same results. So far as ordinary electro-

lytic determinations were concerned he did not think there was much difference whether the electrolyte was stirred independently or whether the stirring was done by means of one of the electrodes. The latter method was certainly the most convenient in electro-analysis.

Mr. HUMPHREYS emphasised that the same degree of accuracy could be obtained with rotating electrodes as with the fixed electrodes. From 18 months' experience with both methods, with regard to the estimation of copper, he assured them that equally accurate results were to be obtained from both methods. The electro-analysis of zinc was much more satisfactory with rotating than with stationary electrodes.

MR. J. A. SCHOFIELD IN THE CHAIR.

METHODS OF CHEMICAL CONTROL IN THE NEW ZEALAND MEAT FREEZING WORKS.

BY ALLISTER M. WRIGHT.

The methods of chemical control in freezing works are of a most varied character, and may be either qualitative or quantitative; qualitative to determine if certain impurities are absent, or whether the colour, odour, or taste of the finished product meet the requirements demanded; quantitative to determine if the products have been economically manufactured, and to make sure that the finished products conform to the guarantee to the purchaser.

In the examination of many by-products empirical methods are adopted which are useful when rapid results are demanded, in other cases more accurate methods must be employed.

Tankage.—In the examination of this, the constituents determined are moisture, tri-calcic phosphate, nitrogen, and fat. The moisture is determined in 2 grms. by heating for three hours in the water oven. Tri-calcic phosphate is determined in 2 grms. by igniting, dissolving in hydrochloric acid, adding ammonia solution until a precipitate is formed, re-dissolving in slight excess of citric acid, and filtering. Magnesia mixture is added and the precipitate allowed to stand two hours before filtering. It is redissolved in hydrochloric acid, and re-precipitated with ammonia, then filtered, ignited, and weighed. Nitrogen is determined in 1 gm. by the Kjeldahl method. The fat is determined in 1 gm. of the substance by treating it with 50 c.c. of carbon tetrachloride in a conical flask, placed in a shaking machine for half an hour, filtering off an aliquot portion, and evaporating. The moisture should not exceed 10 per cent., and in this condition the tankage may be stacked in heaps without heating, and consequent loss of nitrogen.

The percentage of fat and nitrogen serve as important indications of the economical rendering of the raw offal. The fat should not exceed 15 per cent.; a higher proportion indicates over-cooking. The nitrogen contents multiplied by 6.25 should not vary more than 1 per cent. from the organic matter other than fat; a low proportion indicates that the offal has been under-cooked.

The following analyses show the composition of well prepared dried tankage:—

	1.	2.	3.
Moisture, per cent.	10.62	8.24	6.29
Tri-calcic phosphate, per cent.	23.94	11.60	12.12
Nitrogen, per cent.	7.50	10.16	10.08
Fat, per cent.	15.32	14.40	15.96

Dried blood.—In the examination of dried blood, the moisture and nitrogen are determined. The moisture should not exceed 10 per cent., and the nitrogen should be about 15 per cent. Should the moisture exceed this, the blood will rapidly heat, and lose nitrogen. Blood to be economically treated should be cooked and dried

as rapidly as possible after killing, and on the same day; if this is not done a serious loss of nitrogen results.

The following are typical analyses of dried blood:—

	1.	2.	3.
Moisture, per cent.	9.25	8.30	10.20
Nitrogen, per cent.	14.40	14.51	13.96

Tankage and dried blood are used mainly in the manufacture of complete commercial fertilisers.

Tallow.—Tallows are examined for their "titer" or the determination of the solidifying point of the fatty acids which are separated from the tallow. The method used is that recommended by the Assoc. of Official Agricultural Chemists of America, described in Bulletin No. 99, Bureau of Chemistry, U.S. Department of Agriculture, p. 61.

Other determinations are those of water, dirt, which may include portions of animal tissues, and free fatty acids. The titer of first grade tallows will generally lie between 45.5° and 48.5° C., that of second grade between 43° and 45°, and third grade between 40° and 43°.

The acidity ranges between 0.75 and 7 per cent. in good to fair quality tallow, whilst in some samples it may reach 50 per cent.

Wool.—In the examination of wools, the following methods are used:—

Moisture is determined in 1 gm. by drying at 110° C. for one hour in an air oven. After removal from the oven the sample must be placed in a desiccator over sulphuric acid and cooled under vacuum, and thereafter weighed as rapidly as possible.

Natural wool grease is determined by extracting 2 grms. of the wool in hot alcohol, and evaporating an aliquot portion for the total fat. In another portion the free acid is determined, and after deducting this as fatty acids, the balance is considered to be natural wool grease. In another 2 grms. the total fats are extracted with ether, and after deducting the natural wool grease, the balance is entered as other fatty matter. After drying and weighing the wool from the previous determination the sand, dirt, and lime may be approximately determined by shaking them out mechanically, the residue being again dried and weighed as wool fibre. The results so obtained are sufficiently accurate for comparative purposes, and the control work on shod wool.

The following analyses are typical:—

	12.22	13.40	11.08	10.86	12.80	12.74
Moisture, per cent.	12.22	13.40	11.08	10.86	12.80	12.74
Natural wool grease, per cent.	5.42	3.44	7.28	14.54	3.68	11.90
Other fatty matter, per cent.	1.86	1.02	1.62	0.56	1.56	
Sand, dirt, lime, &c. per cent.	5.74	6.42	10.30	7.36	12.26	
Wool fibre, per cent.	4.76	75.72	69.72	66.68	69.70	56.28

Meat extract.—The following determinations are made:—Moisture, ash, fat, substance precipitable by 80 per cent. alcohol, and substance soluble in 80 per cent. alcohol. In addition the taste and colour of the extract are noted. The methods of analysis have been described by the author.* Preserved meats and bacon are principally examined for preservatives (chiefly boric acid) and ptomaines.

Boric acid is determined in 10 grms. of the meat by digesting it in 30 c.c. of concentrated sulphuric acid and 250 c.c. of methyl alcohol with frequent shaking, for two hours, and then subjecting the whole to distillation, more alcohol being added from time to time as the distillation proceeds. After distilling for about 1½ hours, the distillate is diluted with water to a convenient volume; to an aliquot portion is added glycerine, about one-third of its volume, and this is titrated with deci-normal sodium hydroxide, using phenolphthalein as indicator. Various meats showed by this method boric acid content of 0.108 per cent., 0.232 per cent., 0.310 per cent.

In the examination for ptomaines the Stas-Gautier

* This J., 1907, 1229.

method is used.* Indication of ptomaines is rarely found except in blown tins and obviously decomposed meats.

Oleomargarine.—The colour of oleomargarine from mutton fat should be nearly pure white, that from beef fat should be light yellow. There should be no indication of rancidity, and no more than a trace of free acid.

Glue.—In the examination of glue, moisture, ash, gelatin, non-nitrogenous matter, nitrogen, and water absorbed in forty-eight hours are determined. The condition after soaking for forty-eight hours is also observed. The methods of analyses employed are those described by Rideal†. In the drying of glue certain determinations are made to ascertain and regulate the amount of moisture in the air of the dryer. For rapid and fairly accurate work, a "Hygrodeik" is used. This is a wet and dry bulb thermometer, to which is attached an indicator, with a chart upon which the various tables and calculations are plotted, so that the relative humidity and grains of water per cubic foot are shown at once without reference to tables, or further calculation. The following determinations and readings show the moisture, and relative humidity of the air on entering the dryer and on leaving it:—

	Air entering the dryer.		Air leaving the dryer.	
Temperature . . .	64° F.	65° F.	53° F.	54° F.
Relative humidity	40	45	95	93
Grains of water per cubic foot . . .	2.8	3.1	4.4	4.3

Other analyses.—The chemicals used in connection with the treatment of skins, as sodium sulphide, arsenic sulphide, lime, salt, sulphuric, lactic, acetic, and formic acids, must be as free as possible from soluble iron compounds. Lubricating oils, used in connection with refrigerating machinery using anhydrous ammonia, should be non-saponifiable. The author some years ago was consulted with reference to trouble in a refrigerating machine, and found that it arose from the use of a readily saponifiable oil, producing an ammonia soap in the machine. Where steam is used in direct contact with food products, no boiler compound should be used containing volatile organic compounds, as contamination of food has been definitely traced to this source. Hence the feed water must be examined periodically.

The methods herein described are those in use in the laboratory of the Christchurch Meat Company, Ltd., and for permission to read this paper I have to express my thanks to the General Manager.

DISCUSSION.

Mr. L. MEGGITT thought the extraction of fat in tankage with carbon tetrachloride was novel, and he would like to know why this solvent was chosen. With regard to the statement that tankage will not keep if its moisture was over 10 per cent., he would be surprised if it would keep when it contained anything like so much. He did not think the factor 6.25 was a good one for the nitrogen, as the material was not all protein: 6.66 was a truer factor, while for gelatin and glue 5.9 was not far wrong. For the examination of glue he considered that Rideal's methods of analysis gave no indication of the commercial value. The proportion of nitrogen, for example, meant nothing, for a glue worth only £30 might contain the same proportion as one worth £100. Besides colour, taste, smell, and fracture, the "jelly" test alone was valuable, i.e., the comparative stiffness and the viscosity at a definite temperature with varying proportions of water. In determining the acidity of tallow he thought it was usual to dissolve in hot alcohol, and inquired whether the use of ether with the alcohol was to enable the determination to be done in the cold. He considered the methods of the Association of Agricultural Chemists of America were the most up to date and generally

applicable. He agreed with many of the statements of the author, and thought his remarks regarding saponifiable oils in refrigerators were very interesting.

Mr. T. STEEL noticed that for the determination of fat in tankage only 1 gm. was used, and then only an aliquot part of the extract evaporated. To attempt to get 1 gm. to truly represent such an uneven kind of mixture as tankage seemed to be an unsatisfactory procedure. Then with regard to allowing 1 gm. of the wool to cool (after drying) over sulphuric acid in a vacuum and then weighing in the air, he suggested that a stoppered weighing tube would be much simpler and more satisfactory than having refinement at one end and neglect at the other.

Mr. A. A. RAMSAY pointed out that when examining meat extracts for boric acid, which would only be present in small proportion, the distillation method was slow and tedious. He thought the small proportion of boric acid might be extracted with chloroform, or might even be dissolved out with glycerine and titrated at once.

Dr. J. M. PETRIE noticed that in the paper two methods were described for estimating fat—one by extracting with carbon tetrachloride, and the other with alcohol. Recent investigations had shown that it was quite impossible to extract the whole of it. Hot alcohol gave the most complete extraction, while ether only came within 60 per cent. of hot alcohol, and petroleum spirit within 45 per cent. At the same time alcohol extracted too much, dissolving out also such bodies as cholesterol.

Mr. WRIGHT, who was unable to be present, wrote in reply, that he had found by experiment that carbon tetrachloride was as good a fat solvent as ether or petroleum ether, and on account of its non-inflammable nature used it for extraction where rapid determinations were called for. It had been his experience that tankage would keep for at least a year with a moisture content of from 8 to 10 per cent., provided the fat did not exceed 15 per cent. His reason for using ether with alcohol, in the determination of acidity in fats, was that solution was more readily effected. When tankage was finely ground for analysis it could be reduced to a fairly even mixture, and one gm. was sufficient to represent the sample drawn. The suggestion of a stoppered weighing tube was certainly a simpler and more satisfactory method than that described in the paper. He was unable to agree with Dr. Petrie's remarks with reference to petroleum ether as a fat solvent. For tankage especially he had found it most satisfactory, dissolving out practically all the fat, without any of the glycogen which was almost invariably present; this solvent was always used by him when extracting fat from animal tissues with the Soxhlet apparatus. Owing to the nature and diversity of the problems calling for solution in technical analysis as applied to the freezing works, and owing to the limited information afforded by the literature on special branches of chemical technology, it was somewhat difficult for a chemist to devise original methods which would combine scientific accuracy with the rapidity demanded in a works laboratory, and thus maintain a high standard of quality in the products and the economical utilisation of the by-products.

MR. J. A. SCHOFIELD IN THE CHAIR.

THE CIRCULATION OF HEATED LIQUIDS.

BY E. V. MILLER.

Seeing that in industrial operations heat is applied to liquids in a great variety of apparatus, in many of which the rapidity of circulation of the fluid is an important efficiency factor, it becomes a matter of interest to ascertain the precise mechanism of this circulation, i.e., how it is related to the source of heat, to the shape of the heating apparatus, and to other circumstances.

* Mitchell, *Flesh Foods*, p. 298.

† Glue and Glue Testing, pp. 108-135.

Fig. 1.

The question first presented itself in reference to the heating of sugar solutions in a vacuum pan. Fig. 1 shows a section of a type of vacuum pan, where the heating surface consists of copper pipes coiled in nearly flat spirals (shown in section at C), to the inside of which steam under pressure is admitted. There is no communication between the solution and the inside of the pipes, the condensed water which forms in the latter being removed without admixture with the sugar solution. The circulation in such a pan is known to be in the direction indicated by the arrows on the stream line shown. The central space where the liquid descends is called the well.

Circulation before boiling.—Considering now the circulation of the liquid while it is being heated, and before attaining the boiling point, the cause of the movement must be a difference between the mean density of the portion of each stream line, A to B (in the direction of the arrows), and that from B to A, through the well, this being brought about through dilatation of the hotter arm. The ultimate cause of the circulation is, then, that the mean temperature of the portion of stream line A to B is, and continues, greater than the mean temperature of the portion B to A. If we follow a particle of the liquid in its course round a stream line as it starts from A and rises close to the heating surfaces, it will on this portion of its journey be receiving heat, and will rise in temperature until it begins to descend into the well, when, being further from the heating surfaces, it will receive little or no heat, so that it will remain practically at the temperature it had attained at the summit, B, of its course. This cycle will be repeated after it again reaches A.

Now, instead of regarding the heating of a particle as time goes on, consider the temperatures existing at any one instant all round a stream line. In this case, if there is a temperature gradient along the course A to B, there must be an opposite temperature gradient along the course B to A. Thus the difference between the mean temperatures of the two portions of the stream line does not depend, at any rate directly, on the temperatures at A and B, but on some difference in the character of the gradients existing along the two arms of the stream line. The problem can be much simplified by considering an arrangement whereby all temperatures would remain constant as regards time. Fig. 2 represents an endless tube filled

Fig. 2.

with liquid. To the arm ACB a source of heat of constant temperature is applied (say steam in a jacket); while to

the arm BDA, also jacketed, is applied some cooling medium whose temperature can also be kept constant. Time being given for things to assume a steady state, the following conditions will hold:—The velocity of circulation, as measured by the mass passing any cross section of the tube in unit time, will be constant; the rate of accession of heat by the arm ACB from the source of heat will be constant, and will equal the rate of exit of heat from the other arm to the cooling medium; the quantity of heat stored in the liquid will be constant, and the temperature existing at any fixed point of the tube will remain constant as regards time. The whole area of a cross section of the interior of the tube may not be at the same temperature. The temperature at a point of the tube, then, means the mean temperature over the cross section at that point. The temperature gradient means the rate at which the temperature at a point changes per unit length of the tube. Each arm will receive heat, and each will be cooled.

Let T = temperature of the hot source. Let x = distance along the tube in the direction ACB. Then x at A = 0, and x at B = x_1 . t = excess of temperature at any point over that at A. t_0 = temperature at A. t_1 = temperature at B. (Thus the temperature at any point = $t_0 + t$.)

At a point on ACB consider a volume consisting of a length, dx , of the full area of cross section of the stream. There are two influences tending to cause change of temperature throughout this volume. The first is the receipt of heat from the source, and the second is the continual influx of liquid coming from a cooler region. Since the temperature of the volume actually remains constant as regards time, these two influences must be equal and opposite. Expressions may be found for them by considering the effect of each in the absence of the other, as follows:—

Change of temperature by conduction of heat from source.—If movement of the liquid mass were suddenly stopped, the temperature all along ACB would at once begin to increase, the rate of increase being some function of the difference between the temperature of the source and that of the liquid. Probably it will not be far wrong to say that the rate of increase of temperature $\frac{dt}{d\tau}$ (where

τ = time) would be proportional to the difference between the temperature of the source and that of the liquid; and for want of more exact knowledge this will be assumed. We have, then, at a point at which the temperature is $t_0 + t$:—

$$\frac{dt}{d\tau} = k \{ T - (t_0 + t) \} \dots \dots \dots (1)$$

where k is a constant.

Change of temperature by convection.—If we suppose the receipt of heat from the source to suddenly cease while the movement of the liquid continues, the temperature at any point on ACB will at once commence to fall owing to the advent of cooler liquid. The rate of this change will be proportional to the product of the temperature gradient, $\frac{dt}{dx}$, and the velocity; or, since the latter is constant, it will be proportional simply to $\frac{dt}{dx}$. Thus we have

$$\frac{dt}{d\tau} = K \frac{dt}{dx} \dots \dots \dots (2)$$

where K is constant.

Combining (1) and (2) we get $\frac{dt}{dx} + Lt = L(T - t_0)$, where L

stands for k/K ; whence $t = Ce^{-Lx} + T - t_0 \dots \dots \dots (3)$ To find C and L we have the following conditions:—When $x = 0$, $t = 0$, and $C = t_0 - T$; when $x = x_1$, $t = t_1 - t_0 = Ce^{-Lx_1} + T - t_0$, or $Ce^{-Lx_1} = t_1 - T$. Substituting for C , $e^{-Lx_1} = \frac{t_1 - T}{t_0 - T}$, or $-L = \frac{1}{x_1} \log \frac{t_1 - T}{t_0 - T}$, so that, in terms of known quantities

$$t = (t_0 - T) e^{x_1 \log \frac{t_1 - T}{t_0 - T}} + T - t_0.$$

Calculation of a special case.

Let $x_1 = 10$ units of length, $T = 240^\circ \text{ F}$, $t_0 = 140^\circ \text{ F}$, and $t_1 = 150^\circ \text{ F}$. Then $t_1 - T = -90$, and $t_0 - T = -100$, so

that $t = 100(1 - e^{-0.010536x})$. From this the accompanying table of corresponding values of x and t has been calculated. The third column gives the differences of temperature for each unit advance in distance, so that these figures represent approximately the temperature gradients at the different points.

x .	t .	Difference.
0	0.0	—
1	1.0481	1.0481
2	2.0852	1.0371
3	3.1101	1.0249
4	4.1268	1.0167
5	5.1311	1.0043
6	6.1259	0.9948
7	7.1098	0.9839
8	8.0833	0.9735
9	9.0467	0.9634
10	10.0000	0.9533

It will be noticed that the increase of temperature per unit length is greatest near A and falls off as B is approached. This has the effect of making the mean temperature along the arm greater than the average of the extreme temperatures t_0 and t_1 , which is 145° F. A close approximation to the mean temperature will be got by taking the average of those in the middle column (5.0867) and adding t_0 , thus giving 145.0867. This is 0.0867° above the mean of the extreme temperatures.

Or, the true mean temperature, $t_0 + t$, may be derived from the original equation (3), by integrating (i.e., multiplying each value of t by its corresponding dx), and dividing by x_1 , which is the sum of the dx 's. Thus we have, where $t = t_0 + t - t_0$

$$t = \frac{1}{x_1} \int_0^{x_1} Ce^{-Lx} dx + \frac{1}{x_1} \int_0^{x_1} (T - t_0) dx$$

$$= \frac{1}{x_1} \left\{ -\frac{C}{L} e^{-Lx_1} + \frac{C}{L} \right\} + \frac{1}{x_1} \{ (T - t_0) x_1 \}$$

$$= \frac{C}{Lx_1} (1 - e^{-Lx_1}) + T - t_0$$

Taking the numerical values of the special case: $C = -949.137$, $e^{-Lx_1} = 0.9000$, and $T - t_0 = 100$. So we have $t = 100 - 949.137(1 - 0.9) = 5.0863$, and the mean temperature will be 145.0863.

The problem of the mean temperature of the cooled arm is a precise counterpart of the above, and leads to the result that the mean temperature of the liquid in this arm is as much below the average of the temperatures at A and B as the mean temperature of the heated arm is above it. Thus to get the whole difference between the mean temperatures of the two arms we must double t as found for one arm and subtract $t_1 - t_0$. In the numerical example the difference between the mean temperatures of the arms would be $(2 \times 5.0863) - 10 = 0.1726$ ° F.

The curves shown in Fig. 3, plotted from the numerical example, indicate the character of the change of temper-

ature as we pass from A to B and thence from B to A; but in order to make the departure of these curves from straightness visible, the figures after the decimal points in the middle column have all been multiplied by ten.

Regarding the difference in mean temperature of the heated and non-heated portion of the stream lines in a vacuum pan as the cause of the circulation, the above analysis shows how small that difference is likely to be in most cases. Tests of temperatures at points in the vacuum pan corresponding to A and B, when the charge was being heated up, showed that the difference never exceeded 5° F. It follows that the difference in mean temperature in the two arms of a stream line must have been much less than 0.17° F., that found for the numerical example, where the range of temperature was taken as 10°.

Inspection of the curves of Fig. 3 shows that the variation of the temperature gradient along the two arms is the real cause of the circulation, for if this did not vary, i.e., if both curves were straight, then the mean temperature, and consequently the mean density, would be the same in both arms, and no driving force would exist.

If, now, the temperature gradient were prevented from diminishing, or were to be made to increase along ACB, by applying more intense heat to the upper part of the arm, this would reduce the difference between the mean temperatures of the arms, and the circulation would be retarded, or might practically cease, notwithstanding that the range between the temperatures at A and B would be increased, and that more heat would be entering the heated arm per unit time than before. As this result appeared somewhat unexpected the writer attempted to test its truth in the following way:—

Fig. 4 shows an endless tube of glass, such as is sold for demonstration of circulation of liquids. The arms a and b were wound closely with insulated manganin wire in a single layer. There were two coils, the lower one extending from e to f , and the upper from f to g . The whole tube was then wound round with lint as a non-conductor of heat, except about 2½ centimeters at k for

observation. The tube was filled with water containing light particles in suspension. The circulation was observed with a lens arranged so that particles in about the middle of the stream were in good focus, and at the same time marks on the outside of the tube were not too far out of focus to be recognisable. These marks were 2 cm. apart, and the time taken by particles to pass between them was taken by a stop watch. The resistance of the arm circuit e to f was 890 ohms, that of the circuit f to g , 207 ohms. External resistances were added to these two arm circuits to adjust the currents through them, which were in parallel. The supply of current was from a lighting circuit of 105 volts.

Experiment 1.—Equal current in both coils (0.12 amp.). As was expected, this induced rapid circulation at first, but this quickly fell off. The velocity 1½ minutes after starting the current was 5½ cm. per second, but this fell off until, in the period between 15 and 21 minutes from start, the circulation was practically constant at 0.11 cm. per second. The current in the upper coil was then increased to 0.45 amp. This soon began to retard the circulation, so that in 26 minutes from start it was barely perceptible. The glass at k was now just warm to the touch. At 39 minutes the circulation had practically stopped. Immediately afterwards the water suddenly spouted out of the relief tube R with some force, showing that the water in the upper portion of the circulation tube was boiling. The rapid initial circulation was doubtless due to the lack of any opposing temperature gradient in the arms

Fig. 3.

d and *c*. As this became established the circulation settled down to a constant and much slower rate.

Experiment 2.—Starting with cold water again, currents of 0.12 and 0.45 amp. were put on from the start, the larger current being in the upper coil. Much more heat must now have been entering the arms *a* and *b* than in the first experiment, yet the circulation after one minute was only 0.24 cm. per second, and in 3½ minutes this had become reduced to 0.12 cm. per second—about the same as in the first experiment after 13 minutes. In 4½ minutes the circulation was seen to be in opposite directions, the liquid in the upper part of the observation space passing upwards, that in the lower part downwards. Doubtless the resistance winding being taken to the very lowest point of the tube (see Fig. 4), coupled with the fact that there was no circulation of the whole body of liquid to contend against, caused this action. The stoppage of circulation, indicated by theory and thus demonstrated, due to increasing the temperature of the upper portion of the heated arm, is not difficult to understand if we pay attention to what occurs in the other arm. If the portion, *fg*, is made very hot, and consequently light, it will pass on into the arm, *dc*, and soon there will be a column of light liquid in that arm as long as *fg*, or if the circulation does not then stop, longer than the column, *fg*.

In a mass of liquid, a stream line is somewhat differently circumstanced from the tube depicted in Fig. 4, since it would be free to "short circuit." With the heat distribution of the two foregoing experiments, the stream lines would doubtless do this; that is, they would form two circuits, one above the other, corresponding to the two regions of different temperature. In a mass of liquid circulation will only take place between the lowest point of the heating surface and the surface of the liquid, and will not extend to the bottom of the liquid if the heating surface does not extend there. Any liquid below the heating surface will remain stagnant. This refers of course only to liquids before they reach their boiling point, as is illustrated by a later experiment.

Fig. 5.

Circulation when boiling.—Passing now to the case of a liquid when boiling, the following experiment will show that the circulation can no longer be due either to temperature differences or to differences of temperature gradients, but is closely connected with the disengagement of vapour. A, in Fig. 5, is an inverted bell jar, about 7 inches deep, nearly filled with water in which particles were suspended in

order to show the circulation. B is a ¼-inch brass tube, bent into a single coil having a diameter nearly as great as that of the bell jar. The coil could be raised or lowered in the water, and was supplied with high pressure steam at *b*. Starting with the cold water the coil was placed rather low down in the vessel and steam turned on. An immediate but sluggish circulation resulted, the lighter particles rising all round the coil, proceeding to the surface, and returning downwards near the axis of the jar. The heavier particles all settled down into the slight pocket at *a*. The circulation extended only ¼ inch below the coil; the liquid below that was stagnant. In order to avoid unequal heating and risk of fracture of the jar the water was stirred from the bottom from time to time by means of a rod. Immediately after each stirring the heavier particles sank into the pocket again, and in the intervals between the stirrings the liquid below the coil became stagnant. This continued until bubbles of air began to rise up from the coil, when the circulation slightly improved. When the water was nearly boiling the coil was raised to within an inch of the surface. On boiling, a violent circulation was set up, which reached to the bottom of the jar, and

swept the heavier particles into its course. This continued when the coil was raised half an inch, indeed it was not until the coil was right up to the surface of the liquid that the heavier particles again settled down to the bottom. During boiling there was rather less steam supplied than during heating up.

If the temperature gradient along a stream line in this apparatus be considered it will be obvious that it must be zero everywhere, for every portion of the liquid must be at the same temperature within a small fraction of one degree. The very brisk circulation is none the less due to expansion and to gravity, but the expansion is that of the liquid into vapour. One portion of a stream line consists of liquid, and the other of mixed liquid and vapour, which, of course, will have a much smaller density. Unlike the case where the liquid is being heated up before boiling, this rarefied material is not carried to the downward portion of the stream line, but is eliminated at the summit; and this is why, in the apparatus of Fig. 5, the circulation during boiling did not form a short circuit but extended to the bottom of the jar, even though the heating was only taking place at the top, whereas before boiling the circulation was limited to ¼ inch under the coil. An example of this difference is afforded by the process of heating up cold water in a Cornish boiler where the heating surface is chiefly near the surface of the water in the boiler. When the upper part of the water is nearly to boiling point the lower portion is still quite cold, but a few minutes of actual boiling bring all parts to the same temperature.

When liquid boils in any vessel the boiling point is not the same at a depth in the liquid as it is on the surface, on account of the hydrostatic pressure of the liquid. With atmospheric pressure on the surface of the liquid this variation of boiling point is slight, except where the depth of the liquid is great. The working of geysers is explained on this principle. But in a vacuum pan the variation of boiling point from this cause may be considerable. If the absolute pressure on the surface of the liquid is equal to 2 in. of mercury, and if we have water boiling in the pan, its temperature will be about 102° F. But 3 feet under the surface the liquid is under the pressure of the water above it in addition to the pressure at the surface. The total pressure would equal 4½ inches of mercury—more than double the pressure at the surface—and the water 3 feet under the surface could not boil unless its temperature reached about 130° F.

To test this point practically a 16-candle-power electric lamp, properly insulated and protected, was fitted into the interior of a vacuum pan, and a sight glass was also fitted at the end of a tube 10 in. long and projecting that distance into the pan. This was fixed in such a position that the light from the lamp would come through the glass after having traversed 9 or 10 in. of the liquid just over the bottom coil near where it entered the pan. This would be the hottest portion of the coil. On looking through the tube when the lamp was lit up, the lamp and a portion of the surface of the bottom coil could be plainly seen. (See Fig. 6, where *a* is the sight tube, and *b* is the lamp; *c* is a sight glass for observing the surface of the liquid, and *d* is another allowing access of light to it.) On exhausting the air from the pan and recharging (which is done through the pipe, *f*), when the liquid reached the level of the light the latter was obliterated owing to froth, but as the level of the liquid rose the light gradually appeared. Steam was then supplied to all the coils. After some time, when the liquid in the pan was boiling violently on the surface as seen through the upper sight glass, raising a wave about 2 ft.

Fig. 6.

high all round the pan, as shown in Fig. 6, there was so little disturbance at the sight tube that the shape of the lamp filament was quite distinct, in fact, the liquid appeared to be quiescent except for a few very small bubbles, presumably of air, which kept crossing close to the glass. There was no trace of boiling at the coil surface. The temperatures at the surface of the liquid and at the lowest coil were practically the same. Invariably on allowing more liquid to enter the pan through the feed pipe, *i.* clouds of bubbles rushed past the sight glass and completely obliterated the light. These were probably derived from air dissolved in the liquid. On stopping the feed the light appeared again. Similar trials were made on several different occasions of boiling, and in no case was any boiling observed at the heating surface, even when steam was shut off all the upper coils. Then the boiling, clearly enough visible on the surface, was due entirely to the heating surface the hottest part of which was under observation. It is instructive to follow the temperatures round a stream line. These will be constant as regards time, or in the case of solutions will alter slowly with the density. From A, going through the coils towards B, the temperature will increase according to the law already found for the non-boiling period. At the same time the boiling point will decrease as we approach the surface, so that at some point between A and B the increasing temperature will meet the decreasing boiling point and ebullition will take place. Between that point and B all the heat taken up by the liquid from the whole heating surface will be rendered latent by evaporation; and at B, and from B to A through the well, the liquid will be at one temperature. It has been repeatedly found that the temperatures above and below the coils of a boiling liquid in a vacuum pan are so nearly identical that slight irregularities mask any difference there may be. The distance below the surface at which boiling occurs will (other things remaining the same) decrease as the rate of circulation increases, and *vice versa*. For if the circulation is very rapid there will be but slight increase of temperature as the liquid rises among the coils, and it will have to travel to a region of lower boiling point (*i.e.*, nearer the surface of the liquid) before ebullition can occur.

Rapidity of circulation.—The factors which control the rapidity of circulation can now be made clear. The rate depends ultimately, of course, on the rate of transference of heat from the steam in the coils to the liquid outside them. This again is a function of the difference of temperature between the steam and the liquid touching the coils. The maintenance of this difference depends on the heat conductance of the coils, and the rate at which heat can penetrate into the liquid. In the absence of circulation heat would have to penetrate the liquid by conduction only, and, as most liquids are very bad conductors of heat, a steep temperature gradient would be set up in a direction normal to the heating surface. A brisk circulation sweeps this away and causes the temperature of the liquid in contact with the heating surface to approximate to that of the body of the liquid. Thus the rate of heat transference, and therefore the rate of evaporation, depends (in so far as the liquid is a factor in the case) almost wholly on the rapidity of circulation, whereby new portions of the liquid are continually being brought into contact with the heating surface. If the circulation is very efficient the rate of evaporation depends more on the nature (material, thickness, &c.) of the coils. The more it is deficient the more it depends on the nature of the liquid, and not on the coils.

Since, as before shown, any increase in rate of evaporation tends to induce an increase in circulation, while, conversely, any increase in the latter reacts to produce an increase in evaporation, it is clear that by removing as far as possible all obstacles to circulation considerable increase in rate of evaporation may result. There is little doubt, however, that such increase tends to a limit conditioned by the properties of the liquid itself. But even if this were not the case; if circulation, in spite of obstacles, could increase to such an extent as to do away with any temperature gradient in the liquid, normal

to the heating surface, still evaporation would be limited by the conductance of the coils.

The obstacles to circulation consist of the walls of the vessel, the coils and other apparatus with their supports, and the viscosity of the liquid. With homogeneous liquids the latter is constant at a given temperature, but with solutions it increases, sometimes enormously, with the concentration. This introduces a factor which may produce curious results. Very impure sugar solutions become exceedingly viscous on evaporation. In dealing with such a solution in the vacuum pan it is often found that a stage is reached when evaporation almost ceases, notwithstanding that the temperature of the mass of substance in the pan is, and remains, very much (80° to 90° F.) below that of the steam in the coils. This is probably brought about as follows:—Owing to sluggish circulation in the first place, the temperature of the liquid touching any portion of the heating surface is enabled to rise to the boiling point, even though its locus should be deep under the surface. The increase of circulation which this ebullition would tend to bring about would be opposed by an increased viscosity due to the accompanying concentration; and if the effect of the latter should exceed that of the former the circulation would be still further retarded. The liquid in contact with the heating surface would become very concentrated and viscous, and would attain a much higher temperature than would the rest of the liquid in the pan. Thus it is likely that in such cases a non-conducting layer of highly viscous liquid is automatically formed all over the heating surfaces, which nearly stops the entrance of heat into the liquid, and can be but slowly replaced by the feeble circulation which alone can be maintained by the very slow evaporation.

The blowing of steam through the liquid in such a way as to assist circulation is found to expedite evaporation considerably. It is obvious that by increasing the pressure of steam used in the coils, and thereby raising its temperature, the rate at which heat enters the liquid may be increased. If, for instance, the liquid is boiling at 160° F. and the pressure of steam in the coils is 10 lb. per sq. in., then the temperature of the steam will be 240° F., and the difference of temperatures of steam and liquid 80° F. If, now, the steam pressure is raised to 70 lb. per sq. in., which corresponds to a temperature of 316° F., the difference between the temperature of the steam and that of the liquid will be 156° F., or nearly double what it was before. This will cause a much more rapid transfer of heat, not only because at the higher temperature a pound of steam contains more heat, but chiefly because more steam will be used. The resulting increase in evaporation produces brisker circulation, which again reacts on the evaporation, as has been already described. Or, if a very brisk circulation is a desideratum, some of the obstructing heating surface may be removed without reducing the rate of evaporation. The increase of efficiency due to the use of high pressure steam is thus made clear.

Obituary.

WILLIAM MARTIN HABIRSHAW.

W. M. Habirshaw was born February, 1835, in New York City. Previous to the year 1873, Mr. Habirshaw served in the United States Navy as an engineer. Subsequently leaving the navy, he opened a laboratory in New York for commercial analysis and as a chemical and technical consultant, and continued there in that capacity, till about the year 1877. With regard to subsequent years, his services in advancing by improvements and inventions the interests of the iron, sugar, and fertiliser industries have been of great value. He devoted much time and labour to the practical applications of electricity in chemical industry, producing insulating materials which have been in use for many years.

W. M. Habirshaw died on Aug. 15th, 1908, at Saratoga Springs.

He was an original member of the Society of Chemical Industry.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows.—

English.—8s. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars), to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Kilns or ovens; Recovering waste heat from brick, pipe, pottery and other — and utilisation of such waste heat. J. H. Oxley and A. Crossley, Gosmont, Yorks. Eng. Pat. 28,079, Dec. 20, 1907.

A STEAM-JET is fixed in a suitable chamber opening out of the kiln. When the firing is completed, a damper between the kiln and this blast-chamber is opened, the steam turned on, and the hot gases drawn from the kiln by suction and conveyed by pipe or flue to any place required. Pipes conveying the heat to drying chambers are fitted with adjustable outlets, so that the discharge of hot air may be distributed over the whole, or concentrated in any part of the drying room, as desired.

—H. H. S.

Ovens [for pottery, etc.]; Construction of —. A. Parvillée, Paris. Eng. Pat. 18,730, Sept. 7, 1908. Under Int. Conv., Sept. 9, 1907.

IN order to avoid the excessive strains due to rapid heating and cooling, the kiln is built with two walls, the outer being of armoured concrete, and the inner one, constituting the oven proper, of refractory material. The space between the two walls is filled with non-conducting and slightly compressible material, such as iron dross or clinkers mixed with a little sandy clay. The arrangement may be extended to a whole battery of kilns.—H. H. S.

[Incandescence] Heating by radiation; Refractory mantles or the like for —. M. Delage, Paris. Eng. Pat. 28,407, Dec. 24, 1907. Under Int. Conv., Feb. 27, 1907.

A MANTLE knitted from asbestos thread is soaked in a solution of the soluble salts of metals having refractory oxides, dried, and stretched upon a mould to give it the desired form. This is done in order to harden and stiffen the mantle. It is then calcined in a gas flame and a thick layer of cerium oxide is deposited upon it by soaking it in a strong solution of a cerium salt, drying and subsequently calcining it.—W. H. C.

Filtering apparatus; Rotary —. A. J. Arbuckle and A. Osborne, Johannesburg, Transvaal. Eng. Pat. 20,400, Sept. 28, 1908.

A CYLINDRICAL frame, 1, having a solid flange, 2, on its outer edge and a hollow flange, 3, on its inner edge, is divided into several compartments by transverse ribs. It is covered on its inner and outer surface by curved perforated plates, 7, over which filter cloth, 8, is stretched. The compartments do not communicate with one another, and the frame is carried from a hub, 14, by radiating hollow arms, 15, 16. There are four arms for each section of the frame; one for filtering by suction, one for drying by vacuum, and two for back pressure. The hollow arms communicate at their outer ends with the filtering chambers by the hollow flange, 3, which is also divided into compartments to correspond with the filtering chambers; and at their inner ends with hollow passages pierced in the hub. The passages, 18, are for suction and communicate with the chamber, 47 which is connected to a suction producing device. The passages, 19, communicate with the chamber, 51, connected to a vacuum pump, and the passages, 20, communicate with the chamber, 57, connected to a back-pressure pump. The passages are provided with valves, 24, operated by cam-plates, 39, 40, on the face of the plate, 37. The shaft is supported on a bearing, 35, and is rotated by suitable means. The concentric pipes, 32, 50, 56, are connected to the chambers, 47, 51, 57, by stuffing-boxes. The material to be filtered is fed into the trough, 45, into which the cylindrical frame dips, and on rotation, the liquid is sucked through the cloth and the solid matter forms a cake on the surfaces of the chambers. As the rotation proceeds, the chambers emerge from the liquid, the suction passages are closed and the vacuum passages are opened and the deposit is dried by the air drawn through. On continued rotation the vacuum passages are closed, the back pressure passages are opened, and a current of liquid is forced from the interior through the surface of the filters, thus detaching the solids, which fall on to the shoots, 63, 64, by which they are conducted away.—W. H. C.

Filter-press; Continuous —. A. J. Arbuckle, Johannesburg, Transvaal. U.S. Pat. 905,129, Dec. 1, 1908.

the smaller filters, 7. The liquid which passes into the hollow plunger, 16, is withdrawn by the pumps, 23,

and the solids are gradually compacted into the cone, 4, from which they are finally discharged through the pipes, 65, their discharge being facilitated by the blades, 67, driven by the gear, 68. In order to prevent the pores of the filter-cloth from being blocked up, a small portion of the filtrate is forced back through the filters at each upward stroke of 16. This is effected in the case of the plunger, 16, by the partial vacuum produced at the commencement of the upstroke and in the case of the smaller filters by a number of small back-pressure pumps, one of which is connected to each small filter, 7, by a suitable pipe, and which are all operated simultaneously on the upstroke of 16.—W. H. C.

Dryer. J. P. Grupe, Davenport, Iowa. U.S. Pat. 907,993, Dec. 29, 1908.

THE claim is for the provision of a cylindrical stationary extension to the feed end of a rotary drying cylinder. The extension has a transverse plate inclined towards the dryer, through which the feed conveyor tube passes. The vapour outlet pipe is connected to the upper part of the cylindrical extension.—W. H. C.

Evaporator. C. L. Schalitz, San Francisco, Cal. U.S. Pat. 908,028, Jan. 5, 1909.

THE evaporator is divided into a number of superposed communicating evaporating chambers by arched partitions. A steam coil is arranged upon each partition and has an inlet opening into the chamber below and an outlet connected to an exhaust apparatus. Vacuum is created in all the chambers by a suitable device, and the lowest chamber is heated by a steam coil, the admission of steam to which is controlled by a valve operated by a lever which is weighted down by a vessel full of mercury, and is normally closed. A pipe leading from the lowest chamber dips into the mercury. As the vacuum in the chamber increases, the mercury is drawn up into the pipe and the weight acting on the lever becomes less, so that the valve opens and admits the steam to the coil. Consequently the amount of steam admitted depends upon the degree of vacuum existing in the evaporator.—W. H. C.

Evaporating liquids; Apparatus for —. J. L. Schrade, New York. U.S. Pat. 909,460, Jan. 12, 1909.

THE liquid to be evaporated is sprayed into the upper end of a vertical cylinder having an outlet at the top. The lower portion of the wall of the cylinder is perforated and is surrounded by a jacket in which is a steam coil. Air is blown through a perforated pipe into the lower portion of the jacket and displaces the warm air, which passes through the perforations into the cylinder, where it ascends and meets the falling spray of liquid. The liquid is vaporized and is carried away by the upward current of air, the solid particles falling to the bottom of the vessel, from which they are discharged.—W. H. C.

Washing and lixiviation of granular or fibrous materials; Apparatus for —. W. Fink, Ger. Pat. 204,474, July 8, 1906. Addition to Ger. Pat. 202,499.

THE present patent relates to improvements in the apparatus described in the main patent (see Fr. Pat. 369,763 of 1906; this J., 1907, 190), whereby air is forced into the washing liquid and causes a whirling motion of the material, thereby aiding the washing and lixiviation.—A. S.

Columns for distilling and rectifying purposes; Notched —. F. Pampe, Halle on Saale, Germany. Eng. Pat. 26,584, Dec. 2, 1907. Under Int. Conv., Dec. 1, 1906.

SEE Fr. Pat. 384,775 of 1907; this J., 1908, 493.—T. F. B.

Kiln; Rotary —. M. G. Semper, Weferlingen, Germany. U.S. Pat. 909,464, Jan. 12, 1909.

SEE Fr. Pat. 390,586 of 1908; this J., 1908, 1101.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

PATENTS.

Fuel; Artificial —. G. W. Herheim, Seattle, Wash. U.S. Pat. 907,398, Dec. 29, 1908.

PETROLEUM oil is mixed with dried peat, heated, and afterwards mixed with dextrin as a binding agent. The resulting mass is briquetted hot.—W. H. C.

Gas-producer control. B. E. Eldred, Assignor to Combustion Utilities Co., New York. U.S. Pat. 908,454, Jan. 5, 1909.

PRODUCTS of combustion are delivered into a gas-producer by a fan, or other draught-producing device which exhausts the gases from a chimney and delivers them to the producer. The pipe connection on the suction side of the fan has two mechanically operated valves. One of these is open when the fan is working and controls the supply of gas; the other is closed and is connected to the air. When the fan ceases to work, the valves are automatically reversed so that there is no return flow of the gas from the producer to the chimney.—W. H. C.

Gas-producer. J. A. Smitmans, Pittsburg, Pa. U.S. Pat. 908,812, Jan. 5, 1909.

THE generator is divided by vertical partitions into a number of chambers communicating below and open above. A cover provided with a feed hopper and a gas-delivery pipe rests upon the chambers and closes them. This cover can be rotated so that the hopper and gas-outlet pipe each only communicate with one chamber at a time and never with the same chamber at the same time.—W. H. C.

Gas-producer. C. L. Straub, Milwaukee, Wis., Assignor to Power and Mining Machinery Co., New York. U.S. Pat. 909,345, Jan. 12, 1909.

THE producer is provided with an evaporator or boiler below the fuel hopper and above the heating chamber. The latter has a refractory lining which extends horizontally inwards at the top towards the centre, above the bottom of the boiler. The hot gases are caused to circulate over the extended portion of the lining to heat the boiler, and the latter is provided with pipes which pass downward through the wall of the producer and serve to conduct steam from the boiler to the fire zone.—W. H. C.

Gas-producer. P. G. Schmidt, Timwater, Wash. U.S. Pat. 909,690, Jan. 12, 1909.

A NUMBER of adjustable shields are arranged transversely in the body of the producer above the grate. The shields are connected by pipes passing through the top of the producer to an external main by which the gas is conducted to a casing or chamber which surrounds the producer at the level of the grate and from which the gas is discharged. Another pipe connects the space above the fuel with the annular chamber or with the space below the grate and is provided with a valve controlled by a thermostat placed within the producer.—W. H. C.

Gas-producer for heating gas retorts or for other purposes. P. V. Parsy, Fr. Pat. 393,810, Nov. 6, 1907.

IN order to obtain the depth of combustion zone necessary to reduce the whole of the carbon dioxide first formed to carbon monoxide, without using a very deep producer chamber, it is proposed to construct the latter in such a way that the gas and air pass through in a horizontal rather than in a vertical direction. This is effected by making the producer chamber of greater length than depth and by taking away the gas from the back, at the same level as that of the openings by which the air enters at the front of the producer. It is also claimed that owing to the proximity of the zone of combustion to the ash-pit, an increased evaporation of the water supplied to the latter is effected, with a consequent increase in the proportion of water-gas in the gas produced. Further the charging can be effected without allowing a large volume of air to enter the generator, which would reduce the temperature of the combustion zone.—W. H. C.

Mixed gas; Production of — from illuminating gas and water-gas. H. Strache. Ger. Pat. 205,252, July 21, 1906.

THE incandescent coke falls directly from the retorts in which the illuminating gas is produced, into the gas-producing chamber below, and is then treated alternately for the manufacture of producer-gas to be used for heating the gas retorts and of water-gas, which is led into the retorts. During the "hot blow" period, the pressure above and below the junction between the gas-producing chamber and the retorts is kept approximately equal, in order to prevent any appreciable flow of producer gas into the retorts or of illuminating gas into the gas-producing chamber, and thus avoid the necessity of using valves.

—A. S.

Distillation gases; Apparatus for treating —. L. Wolf, Dübendorf, Switzerland. U.S. Pat. 909,125, Jan. 5, 1909.

THE distillation gases are first passed through a cooling apparatus where they are cooled by the expansion and vapourisation of petroleum or gasoline contained in a jacket surrounding the cooler. After the heavier bodies have been condensed, the remaining uncondensable gases are aspirated by a pump and forced under high pressure into the gasoline.—W. H. C.

Gasometers; Protecting the iron walls of — from the action of the cyanogen compounds dissolved out of the gas by the water of the hydraulic lutes. O. Kaysser, Fr. Pat. 393,661, Aug. 26, 1908. Under Int. Conv., Sept. 5, 1907.

POTASSIUM permanganate either alone or mixed with cement is added to the water which forms the hydraulic seal and is stated to convert the cyanogen compounds into bodies which have no deleterious action on the iron.

—W. H. C.

Electrode or pencil for arc-lights. I. Ladoff, Cleveland, Ohio, Assignor to P. C. Peck, New York. U.S. Pat. 909,428, Jan. 12, 1909.

THE claim is for the combination of a positive electrode consisting of an axially disposed iron core surrounded by carbon or graphite, with a negative electrode composed chiefly of "ferrie" and "titanic" material.—W. H. C.

[*Electric*] *Lamps; Process for exhausting* —. M. M. Merritt, Middleton, Mass., Assignor to Boston Incandescent Lamp Co., Danvers, Mass. U.S. Pat. 909,811, Jan. 12, 1909.

A "VOLATILE chemical agent" is introduced into the lamp bulb, which is then connected to a pump and exhausted to the required degree. The filament is then raised to incandescence, whereby the "chemical agent" is partly volatilised while the bulb is still connected to the pump. The bulb is then sealed off and the residual gas is acted on in the presence of the incandescent filament by the "chemical agent" which is completely volatilised.—W. H. C.

Electric incandescence lamps; Metallic filaments for —. F. J. Planchon. Fr. Pat. 393,888, Nov. 9, 1907.

A MASS is prepared by mixing an aqueous or alkaline solution of aluminous matter with an alkaline solution of tungsten or molybdenum sulphide, or with an alkaline sulphotungstate or sulphomolybdate. The mixture is then precipitated by the addition of an acid and the washed precipitate is made into a plastic or viscous mass with water or an alkaline solution and extruded into a thread or filament which is received in a bath of acid. The filament so formed is then finished by any of the usual processes.—W. H. C.

Incandescence body; Preparation of an —. M. von Curnh. Fr. Pat. 393,587, Aug. 21, 1908.

FIBROUS organic materials are saturated with a solution of appropriate rare earths, dried, and broken up. The fragments are then mixed with thorium oxide and with some refractory material (magnesia for preference) and the mixture is made into a paste with a solution of rare

earths. The mass is moulded into suitable shapes, dried, and burned off, when a porous body is obtained which is said to withstand shocks and the pores of which are lined with a film of rare earths which incandesces when the body is heated.—W. H. C.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Pine, fir, birch, and beech woods; Destructive distillation of —. P. Klason, G. v. Heidenstam, and E. Norlin. Arkiv Kemi, Min. och Geol., 1908, 3, [10], 1—17. Chem. Zentr., 1909, 1, 109—110.

PINE and fir woods yield about the same quantity of water; birch wood yields much more, and beech wood occupies an intermediate position in this respect. The charcoal from all four kinds of wood has almost the same composition. The calorific values of the different charcoals are: fir, 7685 eals.; pine, 7695; birch, 7680; and beech, 7655 eals. All four woods yield about the same quantity of acetone, but the two conifers yield only about half as much acetic acid and methyl alcohol as the other two woods. The course of the carbonisation in its relation to time and temperature is represented graphically. Taking 275° C. as the reaction temperature, the thermal effect of the carbonisation was calculated from the heat of combustion of the wood and of the distillation products (both at 20° C.), and the specific heats and heats of evaporation of the constituents. The following were the results:—Cotton, 152 eals.; fir wood, 317; pine, 223; birch, 289; and beech wood, 316 eals.; in the case of the four woods, the thermal effect amounted to about 6 per cent. of the heat of combustion of the wood. The thermal effects of the reactions at higher temperatures were also calculated. The lower the temperature, and the less secondary reactions interfered, the more exothermic was the reaction. The carbonisation of wood is somewhat more exothermic than that of cellulose, for which the heat of reaction amounts to only about 5 per cent. of the heat of combustion. The methyl alcohol is produced from the methoxyl groups of the lignone; both cellulose and lignone yield acetic acid. The calorific value of the combustible distillation gases is, on the average, about 3.8 per cent. of that of the wood.—A. S.

Pyridine; Aqueous solutions of —. E. Baud. Compt. rend., 1909, 148, 96—98.

THE author has determined the freezing points, contractions of volume, the indices of refraction, and the heats of solution of mixtures of pyridine

and water. On freezing the solutions, ice crystallises from those containing from 0 to 55 per cent. of pyridine; a higher hydrate of pyridine crystallises from solutions containing from 55 to 77 per cent. of the base, and a lower hydrate from mixtures between 77 and 83 per cent.; from more concentrated solutions, pure pyridine separates. The mixture containing 83 per cent. of pyridine shows the lowest freezing point, $-68^{\circ}\text{C}.$ and is a eutectic mixture. The various physical data indicate that at least two hydrates of pyridine exist, one with 2 mols. of water and the other with 6 mols. At the ordinary temperature these hydrates are dissociated in solution, as is shown by the rounded form of the thermal curves and the large variation in the heat of solution of pure pyridine inversely with the temperature. The hydrate richest in water is the less stable of the two. There is a striking concordance between the curve of contractions and that of the heats of formation calculated per 100 c.c. of the mixture. The latter values are a measure of the quantity of hydrate existing in a constant volume. The contraction, therefore, would appear to be in close connection with the extent of combination of the two liquids.—J. F. B.

o-Toluidine and *o*-nitrotoluene; Method of determining small quantities of impurities in —. A. F. Holleman. Rec. trav. chim. Pays-Bas, 1908, 27, 458–462.

THE impurity usually encountered in *o*-toluidine is the *p*-compound and the amount of this is estimated by converting the sample into the acetyl derivative and observing the solidifying point. The solidifying points of known mixtures of the acetyl compounds of *o*- and *p*-toluidine are given in the following table:—

Percentage of <i>p</i> -compound.	Solidifying point, $^{\circ}\text{C}.$
0	109.15
1.12	108.45
2.42	107.75
9.58	103.2
13.6	100.8

42.8 grms. of the toluidine to be tested are added slowly to a solution of 25.2 grms. of oxalic acid dissolved in 1 litre of hot water. After cooling to $0^{\circ}\text{C}.$ the crystals are collected on a filter and washed once with a little water. The toluidine is then regenerated from both crystals and filtrate by adding caustic soda and distilling in steam. After separating the oil, the aqueous liquor must be extracted twice with ether to avoid loss. Both portions of toluidine are now converted into the acetyl compound by using, for one grm. of toluidine, 2 c.c. of glacial acetic acid and 1 c.c. of acetic anhydride, evaporating on a water-bath and distilling in a vacuum. The solidifying point of the two portions is determined and the amount of *p*-toluidine deduced from the above table. When the amount of *p*-compound exceeds 1–2 per cent., the toluidine can be directly converted into the acetyl derivative without first preparing the oxalate. The presence of *p*-nitrotoluene in *o*-nitrotoluene is detected by first reducing with iron and hydrochloric acid and treating the resulting toluidine in the above manner.—J. C. C.

PATENTS.

Sulphur-containing petroleum; Apparatus for utilising —. J. E. Eggleston, Assignor to Standard Oil Co., Bayonne, N.J. U.S. Pat. 908,400, Dec. 29, 1908.

THE crude petroleum is caused to pass through a continuous still formed of a series of vessels, the liquid outlet of the first being connected to the liquid inlet of the second, and so on. The stills are heated to different appropriate temperatures and the vapours from each are passed through separate condensers. The hydrogen sulphide is conveyed by a pipe from the ends of the condensers to a furnace where it is burned into sulphur dioxide, which is either converted into sulphuric acid or is utilised in any other desired way.—W. H. C.

Carbonising furnace. E. Lorenz. Ger. Pat. 204,399, Feb. 2, 1908.

THE patent relates to furnaces for the carbonisation of lignite, peat, etc., consisting of several concentric movable cylinders, heated externally, with inner gas spaces or chambers formed by funnel-shaped bells or hoods (see Fig.). Instead of always leading off the distillation gases from the interior of the bells through the pipes, *a, b*, two additional pipes, *c, d*, are provided, communicating with the spaces, *e, f*, between adjacent cylinders. The four exit pipes are provided with flap-valves, and by adjusting these, the gases may be led off either from the interior of the bells or from the spaces, *e, f*. By thus changing the direction of the gases within the furnace at intervals, the bells last considerably longer.—A. S.

Petroleum; Manufacture of a new spirit by the isomerisation of —. A. Testelin and G. Renard. Fr. Pat. 393,554, Aug. 8, 1908.

A THIN regulated stream of petroleum is injected by a jet of high-pressure superheated steam into a coil set in a furnace and heated to from $400^{\circ}\text{C}.$ to $450^{\circ}\text{C}.$ From the coil the steam and vaporised hydrocarbons are caused to pass under considerable pressure through a tube or retort filled with broken pieces of burnt fireclay which is set lower down in the furnace and heated to a full red heat. The petroleum is "cracked" and the products leave the retort through a pipe and loaded valve by which the pressure is maintained. The products, which contain both lighter and heavier hydrocarbons than the original petroleum, are passed through a fractional condensing system where they are separated. Any unchanged petroleum and heavier bodies may be treated over again until they are converted into lighter bodies.—W. H. C.

Hydrocarbon oils or the like; Treatment of — for the production of volatile spirit. J. Noad, East Ham, and E. J. Townsend, London. Eng. Pat. 13,675, June 27, 1908.

SEE Fr. Pat. 393,433 of 1908: this J., 1909, 84.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

PATENTS.

Anthracene derivatives; Production of —. Farbenfabr. vorm. F. Bayer and Co. Fourth addition, dated Aug. 27, 1908 (under Int. Conv., Sept. 2, 1907), to Fr. Pat. 372,676, Dec. 18, 1906 (this J., 1907, 523).

ACETYLATED α -aminoanthraquinone and its derivatives can be converted into pyridones by treating them with the salts of organic acids. The reaction can proceed in the presence of acetic anhydride and it is therefore possible to acetylate α -aminoanthraquinone, or one of its derivatives, and to convert the acetyl derivative into the corresponding pyridone in one operation. Example 1: A mixture of 10 kilos. of *t*-acetylamine-4-chloroanthraquinone, 20 kilos. of fused potassium acetate, and 100 kilos. of nitrobenzene is boiled for 10 hours. The mixture is then cooled and the condensation product which is precipitated, is filtered off, washed with boiling nitrobenzene, and drained. Anthrapyridone is thus obtained in yellow needles, dissolving in sulphuric acid to give a yellow fluorescent solution. Example 2: A mixture of

10 kilos. of finely powdered α -aminoanthraquinone, 20 kilos. of fused potassium acetate, and 100 kilos. of acetic anhydride is boiled until no acetylated aminoanthraquinone remains. The mass is treated with boiling water and the precipitate is filtered off, washed, and dried.

—P. F. C.

Dyestuffs of the Malachite Green series; Process for preparing blue-green to green acid — fast to alkalis. Anilinfarben- und Extrakt-fabr. vorm. J. R. Geigy. Ger. Pat. 204,034, Dec. 7, 1907.

2,6-DICHLOROBENZALDEHYDE or its 3-nitro-derivative is condensed with ethyl (or methyl) benzylanilinesulphonic acid, and the leuco compound oxidised. The chlorine atoms render the dyestuff quite fast to alkali, and only cause slight blueness of shade.—T. F. B.

Leuco-diaminoanthraquinones and diaminoanthraquinones and their hydroxy- and sulpha-derivatives; Preparation of —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 205,149, July 28, 1907.

LEUCO-QUINIZARIN or its hydroxy-derivatives or sulphonic acids are converted by heating with ammonia in aqueous or alcoholic solution into the corresponding leuco derivatives of 1,4-diaminoanthraquinone; oxidation, such as by treatment with concentrated sulphuric acid, converts these into the 1,4-diaminoanthraquinone derivatives. The preparation of 1,4-diaminoanthraquinone and of its 5,8-dihydroxy-derivative and 5-sulphonic acid is described in detail in the specification.—T. F. B.

Anthracene dyestuffs soluble in water; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 205,214, March 5, 1908.

ANTHRACENE dyestuffs soluble in water are obtained by halogenating heteronuclear α -amino- or α -alkylaminoanthraquinonesulphonic acids, and treating the products with mono- or di-alkylamines in presence of catalytic agents such as copper powder. The dyestuff from 2,4-dibromo-1-aminoanthraquinone-5-sulphonic acid dyes mordanted or unmordanted wool fast, clear blue shades.—T. F. B.

Disazo dyestuffs; Process for preparing red —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 205,661, Oct. 5, 1906. Addition to Ger. Pat. 204,102, April 26, 1906.

THE dyestuffs are prepared as described in the principal patent (see Eng. Pat. 9548 of 1907; this J., 1907, 960) except that, instead of using 2,5,7-aminonaphtholsulphonic acid or its acidyl derivatives as final components, the compound of formaldehyde-bisulphite with 2,5,7-aminonaphtholsulphonic acid is employed.—T. F. B.

Sulphide dyestuffs; Process for preparing —. B. Rassow. Ger. Pat. 205,216, Sept. 26, 1907.

DIAMINODIPHENYLMETHANE or its homologues or derivatives, and also symmetrical disubstituted *N*-alkyl derivatives of these compounds, providing they have at least two amino-hydrogen atoms free, are converted into sulphide dyestuffs by treatment with "sulphur sesquioxide" in sulphuric acid solution. 0.4 part of sulphur is added to 15 parts of fuming sulphuric acid (25 per cent. anhydride); 1.5 parts of *p,p'*-diaminodiphenylmethane are then slowly stirred in, the temperature of the mixture being kept below 40° C. After standing for four or five hours, the mass is poured into 80 parts of cold water, the solution is heated until evolution of sulphur dioxide ceases, and the dyestuff is separated in the form of paste. The dyestuffs obtained by this process dye unmordanted cotton dark green shades from sodium sulphide solutions; by oxidation the shades are converted to Bordeaux red or brick red.—T. F. B.

Thioindigo dyestuffs; Process for preparing —. Badische Anilin und Soda Fabrik. Ger. Pat. 205,324, Oct. 3, 1907.

ACETYLENE-*bis*-THIOSALICYLIC acid or its homologues or derivatives, $R(COOR)_2S.CH_2CH_2S.R.COOR$, where *R* represents a benzene or naphthalene nucleus, are obtained

by the action of dihalogen-ethylenes on thiosalicylic acids, etc. They can be converted into thioindigo dyestuffs by treatment with "acid" condensing agents, e.g., sulphuric acid, aluminium chloride, or zinc chloride, etc.—T. F. B.

2-p-Nitrosophenylaminonaphthalene-6,8-disulphonic acid; Process for preparing —. Badische Anilin und Soda Fabrik. Ger. Pat. 205,414, Nov. 22, 1907.

It is known that concentrated hydrochloric acid causes the nitroso group of the nitrosamine of 2-aminonaphthalenes to migrate to the 1-position adjacent to the amino group. It is now found that 2-phenylaminonaphthalene-6,8-disulphonic acid is converted by nitrous acid into a nitrosamine, the nitroso group of which migrates, on standing with hydrochloric acid, to the benzene nucleus, into the *p*-position to the amino-group.—T. F. B.

Sulphide dyestuff; Process for preparing a blue —. Kalle und Co. A.-G. Ger. Pat. 205,391, Oct. 10, 1907.

A SOLUTION of nitrosophenol, obtained by action of nitrosylsulphuric acid on phenol, is added, at a low temperature, to a solution of *p*-chloro-*o*-nitrodiphenylamine in sulphuric acid: after some hours the indophenol is removed from the mixture with the aid of ice, and is heated with sodium sulphide and sulphur at 120° to 130° C. for 20 hours. The resulting dyestuffs dye cotton from sulphide baths clear blue shades, fast to acids.—T. F. B.

[Azo] dyestuffs for cotton; Process for preparing substantive —. Kalle und Co. A.-G. Ger. Pat. 205,421, Sept. 3, 1907.

THE monodazo derivatives of substances of the composition, $C_6H_2.NH_2(1)X(3)SY(6)NH.Acyl(4)$, (where *X* is alkyl, alkyloxy, or halogen, and *Y* an alkyl, aryl, or CH_2COOH group), are combined with Cleve's α -naphthylaminosulphonic acid, and the resulting monoazo dyestuff is diazotised and combined with naphthols or their derivatives and then saponified. The dyestuffs thus obtained dye cotton reddish-blue shades, which can be developed on the fibre by means of β -naphthol, when fast, pure greenish-blue shades result.—T. F. B.

Intermediate products and colouring matters [thioindigo dyestuffs] containing sulphur; Manufacture of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 90, Jan. 1, 1908. Addition to Eng. Pat. 26,053, Nov. 25, 1907.

SEE Fr. Pat. 385,044 of 1907; this J., 1908, 497.—T. F. B.

Anthracene dyestuff and process of making same. M. H. Isler, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 909,809, Jan. 12, 1909.

SEE Fifth Addition of Feb. 8, 1908, to Fr. Pat. 309,503 of 1901; this J., 1908, 851.—T. F. B.

Monoazo dyestuff and process of making same. W. König, Ohndorf, Assignor to E. Merz, Frankfurt, Germany. U.S. Pat. 908,580, Jan. 5, 1909.

Extracting dyewoods, etc. Ger. Pat. 205,253. See XIV.

Regulations, dated December 30, 1908, for the manufacture of nitro- and amino-derivatives of benzene and the manufacture of explosives with use of dinitrobenzol or dinitrotoluol. Statutory Rules and Orders, 1908, No. 1310. [T.R.]

REGULATIONS 1 (a), 2, 3, 4, and 14 (c) do not apply to any process in the manufacture of explosives in which dinitrobenzol is not used.

Part I.—Duties of Occupiers.

1. (a) Every vessel containing any substance named in Schedules A or B shall, if steam is passed into or around it, or if the temperature of the contents be at or above the temperature of boiling water, be covered in such a way

that no steam or vapour shall be discharged into the open air at a less height than 20 feet above the heads of the workers.

(b) In every room in which fumes from any substance named in Schedules A or B are evolved in the process of manufacture and are not removed as above, adequate through ventilation shall be maintained by a fan or other efficient means.

2. No substance named in Schedule A shall be broken by hand in a crystallising pan, nor shall any liquor containing it be agitated by hand, except by means of an implement at least 6 feet long.

3. No substance named in Schedule A shall be crushed, ground, or mixed in the crystalline condition, and no cartridge filling shall be done, except with an efficient exhaust draught so arranged as to carry away the dust as near as possible to the point of origin.

4. Cartridges shall not be filled by hand except by means of a suitable scoop.

5. Every drying stove shall be efficiently ventilated to the outside air in such manner that hot air from the stove shall not be drawn into any workroom.

No person shall be allowed to enter a stove to remove the contents until a free current of air has been passed through it.

6. A Health Register, containing the names of all persons employed, shall be kept in a form approved by the Chief Inspector of Factories.

7. No person shall be newly employed for more than a fortnight without a certificate of fitness granted after examination by the surgeon by signed entry in the Health Register.

8. Every person employed shall be examined by the surgeon once in each calendar month (or at such other intervals as may be prescribed in writing by the Chief Inspector of Factories) on a date of which due notice shall be given to all concerned.

9. The surgeon shall have power of suspension as regards all persons employed, and no person after suspension shall be employed without written sanction from the surgeon entered in the Health Register.

10. There shall be provided and maintained for the use of all persons employed:—

(a) Suitable overalls or suits of working clothes which shall be collected at the end of every day's work, and (in the case of overalls) washed or renewed at least once every week; and

(b) A suitable meal room, separate from any room in which a process mentioned in the Schedules is carried on, unless the works are closed during meal hours; and

(c) A suitable cloakroom for clothing put off during working hours; and

(d) A suitable place, separate from the cloakroom and meal room, for the storage of the overalls;

For the use of all persons handling substances named in the Schedules:—

(e) India-rubber gloves, which shall be collected, examined, and cleansed, at the close of the day's work and shall be repaired or renewed when defective, or other equivalent protection for the hands against contact;

For the use of all persons employed in processes mentioned in Schedule A:—

(f) Clogs or other suitable protective footwear.

11. There shall be provided and maintained in a cleanly state and in good repair for the use of all persons employed:—

A lavatory under cover, with a sufficient supply of clean towels, renewed daily, and of soap and nail brushes, and with either:—

(a) A trough with a smooth impervious surface, fitted with a waste pipe without plug, and of such length as to allow at least 2 feet for every five such persons, and having a constant supply of warm water from taps or jets above the trough at intervals of not more than 2 feet; or

(b) At least one lavatory basin for every five such persons, fitted with a waste pipe and plug or placed in a trough having a waste pipe, and having either a constant supply of hot and cold water or warm

water laid on, or (if a constant supply of heated water be not reasonably practicable) a constant supply of cold water laid on and a supply of hot water always at hand when required for use by persons employed;

For the use of all persons employed in processes mentioned in Schedules A and B:—

(c) Sufficient and suitable bath accommodation (douche or other) with hot and cold water laid on and a sufficient supply of soap and towels. Provided that the Chief Inspector may in any particular case approve of the use of public baths, if conveniently near, under the conditions (if any) named in such approval.

12. No person shall be allowed to introduce, keep, prepare, or partake of any food, drink, or tobacco in any room in which a process mentioned in the Schedules is carried on.

Part II.—Duties of Persons Employed.

13. Every person employed shall:—

(a) Present himself at the appointed time for examination by the surgeon as provided in Regulation 8;

(b) Wear the overalls or suit of working clothes provided under Regulation 10 (a), and deposit them, and clothing put off during working hours, in the places provided under Regulation 10 (c) and (d);

(c) Use the protective appliances supplied in respect of any process in which he is engaged;

(d) Carefully clean the hands before partaking of any food or leaving the premises;

(e) Take a bath at least once a week, and when the materials mentioned in the Schedules have been spilt on the clothing so as to wet the skin. Provided that (e) shall not apply to persons employed in processes mentioned in Schedule C, nor to persons exempted by signed entry of the surgeon in the Health Register.

14. No person employed shall:—

(a) After suspension, work in any process mentioned in the Schedules without written sanction from the surgeon entered in the Health Register;

(b) Introduce, keep, prepare, or partake of any food, drink, or tobacco, in any room in which a process mentioned in the Schedules is carried on

(c) Break by hand in a crystallising pan any substance named in Schedule A, or agitate any liquor containing it by hand, except by means of an implement at least 6 feet long;

(d) Interfere in any way, without the concurrence of the occupier or manager, with the means and appliances provided for the removal of the fumes and dust, and for the carrying out of these Regulations.

Schedules.

A. Processes in the manufacture of:—Dinitrobenzol; dinitrotoluol; trinitrotoluol; *p*-nitrochlorbenzol.

B. Processes in the manufacture of:—Aniline oil; aniline hydrochloride.

C. Any process in the manufacture of explosives with use of dinitrobenzol or dinitrotoluol.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES YARNS, AND FIBRES.

Silk: Action of light on weighted — E. Ristenpart, *Z. angew. Chem.*, 1909, 22, 18–21.

WHILST the mechanical resistance of silk may be regarded as a function of the degree of weighting, its behaviour under the influence of light is more complicated. It is well known that the fibroin of pure silk undergoes a profound change on prolonged exposure to light, and is finally disintegrated; it is also known that certain substances, such as tannin or ammonium thiocyanate, are capable of inhibiting this change. The author has investigated the result of exposing weighted silk to the action of light between the months of March and August. These silks

were loaded respectively to the extent of 136 and 159 per cent. (on the weight of the silk) with tin in combination as phosphate and silicate. At the end of the period of exposure, the silks were treated (a) for one hour with 10 per cent. hydrochloric acid; (b) for 5 minutes with a cold normal solution of sodium hydroxide, and the percentage of soluble matters in each case was determined; similar determinations were also made on unexposed samples of the same silks. The results showed that the loading, in the form of stannic phosphate and silicate, underwent no change under the influence of light, but on the other hand, the fibroin was considerably decomposed. In the sample weighted to 159 per cent., 10 per cent. of the fibroin had been converted into products soluble in the above reagents; in the more lightly weighted sample, 22 per cent. of the fibroin had been converted. Thus a certain degree of protection was afforded by the heavier loading. Another silk was investigated which contained an organic loading, *viz.*, catechutannin in association with stannic oxide and sodium phosphate. In this case it was found that the tannin afforded an absolute protection to the fibroin against the disintegrating action of light, but that a change took place in the condition and solubility of the stannic oxide of the loading. Owing to the method employed for fixing the loading, with a moderately cold, weak solution of phosphate, after the tannin and stannic chloride had been absorbed, the bulk of the tin existed in the silk in the form of stannic oxide, and only a little as phosphate. The action of the light on the stannic oxide was found to convert it into metastannic acid, which is far less readily soluble in hydrochloric acid than the stannic oxide. In this sense the action of light resembles that of prolonged storage. The author concludes that the mechanical deficiency of weighted silk is a far more important practical consideration than the destructive influence of any degree of exposure to light to which the silk is likely to be subjected in practice. The latter is of scientific interest only, and is explained by the author as the result of atomic vibrations in the fibroin molecules, synchronising with those of the waves of light, with ultimate rupture and rearrangement of the groupings. The protective action of tannin, &c., is ascribed to similar vibration periods in the molecule of the protective substance, which divert the action of the light waves from the fibroin. It would appear that the quantity of protective agent present is of no importance as regards the effect, and that the substance is not destroyed in the process; it may therefore be described as a "negative catalyst" or stabiliser.—J. F. B.

Silk; Action of hydracids and their salts on —. P. Sisley. *Rev. Gen. Mat. Col.*, 1909, 13, 4—8.

GNEHM, Roth, and Thomann found that the characteristic stains which appear on silk fabrics on storing, were similar to those produced purposely by the action of perspiration, and in 1897 the author proved that they were due to the sodium chloride in perspiration, his work being confirmed by that of many other chemists. Later, it was found that on patterns spotted with a solution of sodium chloride and stored at different altitudes, different periods of time elapsed before the stains were produced, the longest period being at the highest altitude. Patterns of silk were then treated with a 2½ per cent. solution of sodium chloride and stored in the laboratory, part at 40° C., and part at the ordinary temperature (in sealed vessels to prevent their drying). Both in the case of weighted and of unweighted silk, there was as much loss of tensile strength caused by storing for 1 month at 40° C. as by keeping for 1 year at the ordinary temperature, though the effect was considerably greater on the weighted patterns. Concentrated salt solutions did not produce the stains, numerous experiments having shown that the effect ceased when the quantity of salt was greater than could be dissolved by the moisture contained in the fibre. Other chlorides and hydrochloric acid also produced the stains. It is probable that in the case of the salts, hydrolysis took place first with liberation of hydrochloric acid; for, on treating a weighted pattern, dyed with a colour very sensitive to acids, with a 2½ per cent. solution of sodium

chloride and then drying, the acid reaction was given. In the case of weighted silk, it is probable that the metal liberated from the salt combined with the acid in the weighting and left the hydrochloric acid free, thus explaining why weighted silk was stained more readily. This was borne out by the fact that on unweighted silk treated with sulphuric acid, the stains were produced as quickly as on the weighted. Hydrobromic acid and bromides produced the stains, though less rapidly. Hydrofluoric acid and hydriodic acids and their salts did not stain.

The author's theory is that the liberated acid is oxidised, with production of the halogen, for the stain is instantly produced by dilute chlorine or bromine water. Further, those dyestuffs which are not affected by chlorine are found to be those which are not discharged at the stained places; while, on impregnating silk with a 1 per cent. solution of methyl-*p*-aminophenol, a substance readily turned brown by oxidation, and then spotting with a 2½ per cent. solution of sodium chloride, a brown stain was produced in less than 12 hours. Georgevics and Mueller have shown that the iron present in the fibre is in the ferric condition at the stains and in the ferrous state elsewhere and this is confirmed by the author. It is impossible to obtain silk fibre containing no iron, but experiments with both weighted and unweighted patterns showed that the rapidity of staining did not increase with the percentage of iron, which does not therefore act as a catalytic agent in the oxidation. Meister in 1905 published the theory that copper acts as a catalytic agent. The author, however, finds that silk containing no copper is stained just the same, and considers that the porosity of the fibre aids the oxidation. Wool fabric spotted with sodium chloride and stored, was dyed deeper at the spots, thus indicating the action of chlorine, while stains were produced on a dyed film of albumin similar to those on dyed silk. Thus, the effect seems to be common to albuminous substances.—H. P. P.

Artificial silk; Proposed new French import duties on —. See Trade Report.

Artificial fibres; The dyeing of —. V. Clement. *Färber-Zeit.*, 1909, 20, 1—4.

THE artificial fibres of commerce comprise not only the artificial silks, but artificial horse-hair, straw-plaits, mixtures of non-lustrous curly waste from artificial silk manufacture with wool or shoddy, and similar waste carded and spun by itself. Denitrated collodion silk has a much stronger affinity for basic dyestuffs than "Glanzstoff" or viscose silks; and full shades can be dyed direct on the former, whereas the latter must be mordanted with tannin. If the dye-bath be too hot, there is a loss of lustre and the threads stretch unequally. The optical properties of cellulose, *e.g.*, its double refraction, cause many dyestuffs to fluoresce so strongly that they are unsuitable for artificial silk. All the artificial silks possess the defect, when dyed in bulk or in the cloth, of giving stripes of different intensities of shade. In the collodion silks this defect has been traced to differences in the percentage of residual nitrogen (1.16 to 1.61) remaining after denitration, the darker shades corresponding to higher percentages of nitrogen. In the case of "Glanzstoff" and viscose silks, the darker stripes correspond with a more pronounced oxycellulose reaction. The author thinks that the differences are not due to any irregularities of the chemical treatments subsequent to the formation of the threads, but are caused by uncontrolled changes in the cellulose, taking place under the influence of the alkaline agents employed for dissolving the cellulose prior to spinning. The product of every batch is stated to be uniform as regards its dyeing properties, but is always irregular in count ("denier"). Since this cannot be controlled, the skeins are sorted according to "denier" afterwards, and skeins from several batches are parcelled together, one batch having a different affinity for dyestuffs from another. Artificial silks must be bleached rapidly; alternate treatments with sodium hypochlorite and hydrochloric acid give the best results; the permanganate

bleach weakens the fibre. For dyeing, the basic dyestuffs of the "Janus" group give the best results as a rule. On collodion silks the "Janus" colours give full shades direct, fast to light and to water; the other silks show equally good results on tannin mordants. The "Seto" dyestuffs are also good but not particularly fast. Many of the acid dyestuffs are suitable for the direct dyeing of pale shades, fast to light but not to water. The substantive dyestuffs are used very extensively, but are not suitable for "navy blue"; this colour is best obtained by Janus Blue R or Indoin Blue toned with Methyl Violet. For black, Janus Black gives the finest shades. All dyestuffs are somewhat less fast to light on artificial silk than on cotton. The author concludes with a table of tests for the artificial silks. It is difficult to distinguish between "Glanzstoff" and viscose silks; the latter, however, gives a somewhat darker shade with Schiff's reagent than the former.—J. F. B.

Pieric acid and fibre colloids; Reaction between —. W. P. Dreaper and W. Stokes. J. Soc. Dyers and Col., 1909, 25, 10—12.

THE loss of colour of free pieric acid, under the influence of a dehydrating agent in a vacuum is well known, and the authors have now investigated the effect of similar conditions upon the colour of the dyeings of the acid upon various fibres. The dehydrating agents employed were sulphuric and phosphoric acids and the loss of colour is expressed in percentages of the original shade. These percentages were arrived at by comparison of the shades with a standard set, prepared by dyeing with known percentages of dyestuff. Dyed upon silk and wool, there is no change in the colour even after 52 days, but upon artificial silk, guncotton, and cellulose a loss of colour is noticeable in 3—10 days, and in 52 days amounts to as much as 25—50 per cent. With artificial hair the loss is not so rapid, but this is assumed to be a consequence of the physical condition of the material. There is also a marked difference in the behaviour of the acid when dyed upon silk at the boil, or in the cold; when dyed at the boil, the shade remains unaffected under the conditions of the experiment, but when dyed cold and then exposed, the loss of colour amounts to 12 per cent. after 34 days. In the presence of phosphorus pentachloride, the colour is completely destroyed both upon animal and vegetable fibres, but in all cases the shade resumes its original intensity when the affected dyeings are exposed to a moist atmosphere.—F. M.

Casein and its applications. F. W. Richardson. J. Soc. Dyers and Col., 1909, 25, 4—8.

IN the sizing of cotton warps, Carmichael has proposed the use of a mixture containing casein, 16 parts; soap, 8 parts; mineral or other oil, 60 parts; loading, 200 parts; water, 300 parts. A good dressing for cotton and linen fabrics is said to be obtained by dissolving casein with lime, and mixing this solution with that of a hard soap. A method of waterproofing with casein has been suggested, the claim being that the goods are impervious to water but remain quite permeable to air, and are therefore more suitable in wear than rubberproofed goods. According to a French patent the goods are impregnated with an alkali salt of casein, treated with formaldehyde and dried, and then steamed. Such a treatment may be suitable as a "finish," but for waterproofing, Chevallot recommends a mixture of 40 parts of casein with 200 parts of water, to which is added 1 part of slaked lime and 20 parts of soap dissolved in 240 parts of water. The goods are impregnated with this liquor, passed through a solution of aluminium acetate, dried and ironed. In calico printing, casein may with advantage replace albumin, especially in those cases where the colour of the latter is a drawback, or a diminution in the time required for fixing the colours by steaming is desired. In the discussion following the paper, mention was made of the production of non-inflammable photographic films from acetylcellulose and from casein, also the possibility of employing casein to "animalise" cotton so that this should dye like wool.—F. M.

PATENTS.

Decoration of fabrics. M. Ratignier and H. Pervillae et Cie. First Addition, dated April 2, 1908, to Fr. Pat. 393,412, Oct. 25, 1907.

For the purpose of decorating fabrics according to the process described in the principal patent (this J., 1909, 88), any substance which can be mechanically moulded may be employed. Further the employment of flocks with openwork materials is not essential.—P. F. C.

Dyeings; Production of orange — [by means of azo dyestuffs]. Badische Anilin und Soda Fabrik. Fr. Pat. 393,580, Aug. 21, 1908. Under Int. Conv., Oct. 23, 1907.

FABRICS dyed in the usual way with Primuline are diazotised and treated with a solution of 1,3-dihydroxyquinoline or its salts; e.g., for 2 per cent. Primuline dyeings the solution may consist of 1 per cent. of dihydroxyquinoline in the form of its disodium salt, and 1.5 per cent. of "calcined" sodium carbonate. The orange dyeings produced are fast to light, washing, and acids.—T. F. B.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Calcium carbonate; Dissociation of —. D. Zavrieff. J. Chim. phys., 1909, 7, 31—57.

AT the atmospheric pressure the dissociation of calcium carbonate is rapid and complete at 910° C. The curve of dissociation pressures shows that between 700° and 950° C. there is no intermediate phase produced; and the reaction between those temperatures is reversible. At lower temperatures, the reaction is very slow, and its progress depends upon the nature of the surface of the lime or carbonate, so that definite results are difficult to obtain. Between 500° and 600° C. the intermediate substance,

(CaO) $_2$ CO_2 , mentioned by Raoult is possibly formed, but the results do not definitely show its formation; at these and lower temperatures, however, solid solutions are certainly formed, and these solid solutions, when they contain a large excess of lime, have always lower dissociation-pressures than the carbonate itself, and the reaction is not completely reversible.—J. T. D.

Sulphates, sulphites, and thiosulphates: Detection of —. W. Alexandrow. Z. anal. Chem., 1909, 48, 31–32.

For the detection of sulphates, sulphites, and thiosulphates in the presence of each other, about 0.1 gm. of the substance to be tested is dissolved in a little water, and an excess of barium nitrate, dissolved in 50 c.c. of water, is added in small quantities to the boiling solution. The liquid is then further boiled and allowed to stand for some hours, when the sulphate is completely, and the sulphite partially, precipitated, and barium thiosulphate remains in solution. The precipitate is examined by a known method, and the filtrate is precipitated with silver nitrate solution and allowed to stand for 30–40 minutes, until the silver thiosulphate has been decomposed. Then a little ammonia is added, the silver sulphide is filtered off, and the excess of silver removed from the filtrate by adding hydrochloric acid and filtering again, without heating. Ammonium chloride is added to the filtrate, until any cloudiness disappears, and the clear liquid is then oxidised with bromine water: the presence of a sulphite is indicated by a precipitate of barium sulphate.—F. SOPX.

Hydrosulphides, sulphides, and polysulphides of ammonium, sodium, and potassium. W. P. Bloxam. Z. anorg. Chem., 1908, 60, 113–122.

IN the recent work of Küster and Heberlein on polysulphides (this J., 1905, 544), no reference was made to previous work by the author (this J., 1899, 684), who had shown that aqueous solutions of normal sulphides are quite unsuitable for the preparation of pure alkali polysulphides, some thiosulphate being always formed in addition. Pure polysulphides can be obtained by dissolving sulphur in a solution of the alkali hydrosulphide. The author recapitulates his previous work and describes also the preparation of some ammonium polysulphides. If a moderately strong solution of so-called ammonium sulphide, which, however, is stated to be really a solution of $(\text{NH}_4)_2\text{S} \cdot 2\text{NH}_4\text{HS} + 2\text{NH}_4\text{OH}$, is warmed with excess of sulphur in an open vessel, a deep red solution is obtained, containing tetra-ammonium enneasulphide, $(\text{NH}_4)_9\text{S}_9$. The same compound is obtained if hydrogen sulphide be led into a solution containing ammonia and sulphur in the proportions corresponding to the formula, $(\text{NH}_4)_2\text{S} \cdot 2\text{NH}_4\text{HS} + 2\text{NH}_4\text{OH}$. If sulphur is dissolved in the "ammonium sulphide" solution in the cold, hydrogen sulphide is evolved, and crystals of tetra-ammonium heptasulphide, $(\text{NH}_4)_4\text{S}_7$, are formed. The simple or di-ammonium polysulphides hitherto obtained are probably all secondary products formed by the decomposition of tetra-ammonium enneasulphide under different conditions of temperature and concentration.—A. S.

Alums. R. Marc. Z. anorg. Chem., 1908, 60, 93–207.

A SAMPLE of potassium alum, of which the solubility at 0° C. was about 4.3 grms. in 100 c.c. of water, was not capable of readily yielding supersaturated solutions, a solution of 8 grms. in 100 c.c. of water at 18° C. crystallising when left overnight. This alum behaved in a similar manner after recrystallisation from a hot saturated solution. Experiments showed that the apparent solubility of this alum was a function of the concentration of the supersaturated solution from which the crystals were obtained. That is, if solutions of different concentration were caused to crystallise at the same temperature, by sowing with small crystals, the separation of crystals ceased at different concentrations in the different cases, the solubility being greater, the greater the initial concentration of the solution. This is attributed to the fact that the alum separated from relatively dilute solutions contains appreciably more alkali, i.e., is more basic, than that separated from a concentrated solution. This increase of basicity does not affect the crystalline form,

In comparing alums, the proportions of alkali and of sulphuric anhydride in the salt are not of so much importance as the ratio of sulphuric anhydride to alkali oxide. In the present case this ratio was 3.394 in the original sample (theoretical ratio, 3.108), but fell to 2.166, 2.321, etc., after recrystallisation. Addition of a small quantity of sulphuric acid had no effect on the properties of the alum.—A. S.

Silicate melts: Relation between viscosity and chemical composition of —. E. Greiner. N. Jahrb. f. Mineral., 1908, 11., 152–153. Chem. Zentr., 1909, 1, 258.

THE raw materials used in the experiments were silica, magnesia, aluminium and boron hydroxides, ferric oxide, ferrous, calcium, sodium, and potassium carbonates, and sodium tungstate. The melts were prepared in unglazed porcelain crucibles, 8 cm. high and 6 cm. wide at the top. It was found that in mixtures of metasilicates, Na_2SiO_3 ; $\text{R}''\text{SiO}_3$ or $\text{R}_2''(\text{SiO}_3)_2$, the viscosity, at a given temperature, increases in the following order: FeSiO_3 , MnSiO_3 , $\text{Fe}_2(\text{SiO}_3)_3$, MgSiO_3 , CaSiO_3 , $\text{Al}_2(\text{SiO}_3)_3$. Potassium metasilicate when mixed with silica gives products considerably more viscous than those obtained with sodium metasilicate. The viscosity of an acid melt of the composition, $\text{Na}_2\text{SiO}_3 \cdot \text{SiO}_2$, is lowered by the following oxides, arranged in the order of the effects they produce: FeO , MnO , Fe_2O_3 , MgO ; it is increased by lime and alumina. In general an increase of the basic constituents of a melt causes a decrease in the viscosity; the addition of one-third equivalent of ferric oxide to one equivalent of sodium metasilicate increases the viscosity; alumina acts in the same manner and with nearly as great effect as silica. Silica always causes an increase in the viscosity; boron trioxide and especially tungsten trioxide cause a decrease. No definite relation could be found between the viscosities of mixtures of the series, MgSiO_3 ; Na_2SiO_3 and CaSiO_3 ; Na_2SiO_3 , and the melting points of the components (compare Doelter, this J., 1908, 900), nor between the viscosities of complex melts and those of the silicates which might be regarded as components of such melts. The viscosity (η) may be expressed by a simple modification of Grätz's formula, $\eta = \frac{K}{1 - C^t}$, where t is the temperature and K and C are two constants, depending upon the nature of the melt. It is probable that as the temperature rises, the viscosity tolerably soon reaches a limiting value.—A. S.

Deacon {chlorine} process. K. Vogel v. Falkenstein. Z. physik. Chem., 1909, 65, 371–379.

IN practice, working at 430° C. and with a mixture of hydrochloric acid and air containing 60 per cent. of the latter, 70–71 per cent. of the hydrochloric acid used may be converted by the Deacon process into chlorine. This is the maximum limit indicated by a study of the equilibrium concerned (this J., 1907, 687). But by dehydrating the gaseous mixture, after cooling, by means of strong sulphuric acid, and then reheating at 430° C., the yield of chlorine is increased to 82.5–85 per cent., and a repetition of this treatment gives a yield of 87–89 per cent. of chlorine.—F. SOPX.

Sulphur: Compounds of — with chlorine. E. Beckmann. Z. physik. Chem., 1909, 65, 289–337.

BESIDES sulphur monochloride (S_2Cl_2), already known, the existence of the dichloride (SCl_2) and tetrachloride (SCl_4) has been definitely established. Chlorine has no appreciable action on sulphur monochloride at –33° C., but at –15° C. the dichloride is formed, and by fractionating the product at 4 mm. pressure, 80–90 per cent. of this compound distils over at –24° C. Sulphur dichloride is a dark red-brown liquid, and to it is due the dark colour of old samples of sulphur chloride. When pure, it boils without decomposition at 59° C. It begins to solidify at –80° C., and at –88° C. is an orange-yellow waxy solid which melts again at –78° to –54° C.; polymerisation probably accounts for this behaviour. Its density at 15° C. is 1.622. Chlorine combines readily with sulphur dichloride, giving the tetrachloride, which becomes solid at –70° C. and commences to melt again at –30° C. In the liquid state it readily parts with chlorine

and can only be kept in sealed vessels; it is paler in colour than the dichloride. The boiling point of sulphur monochloride is 137° – 138° C. and its melting point, -75° to -76° C.; its cryoscopic constant is 53.6° C. The molecular weights of the monochloride and dichloride respectively correspond to the formulæ given above.

—F. SODN.

Calcium cyanamide. Eng. and Min. J., Jan. 1, 1909. [T.R.]

THERE are 11 plants in Europe for making calcium cyanamide in process of construction, or in operation, the aggregate annual capacity of which is 166,000 tons. The works at Pianod'Orta, Italy, is being enlarged to increase its production from 4000 to 10,000 tons. In France, the Société Française des Produits Azotés is producing 4000 tons per year at its work at Notre Dame de Briançon. Other works of varying capacities exist in Italy, Switzerland, Germany and England. The initial plant of the American Cyanamide Company is in course of construction at Niagara Falls, Ontario, and it is anticipated that production will begin early in the spring of 1909. On the basis of 10 per cent. nitrogen content, the initial capacity of the half-unit plant at Niagara Falls will be 20,000 tons per annum. This cyanamide will yield from 12 to 15 per cent. of ammonia. In deference to requirements of American trade, free lime will be eliminated, and the nitrogen content reduced as compared with the European product.

Determining nitric acid. Hes. See XXIII.

Determining sulphite. Milbauer. See XXIII.

PATENTS.

Sulphuric acid; Simultaneous manufacture, concentration, and purification of —. G. C. de Briailles. Fr. Pat. 393,665, Oct. 31, 1907.

bottom of the vessel (1), respectively, thoroughly gas-tight joints being assured between (2) and (5) on the one hand, and between (5) and (1) on the other. Through the tube (2), which is fitted with a tap (6), a current of sulphurous acid, liquefied or in solution, is forced under pressure into the porous vessel (1). The latter is surrounded by a lead container (7), cold water circulating inside the intervening space. The tube (2), and the container (7), serve as positive and negative electrode respectively, and are insulated from one another by a rubber ring (8), surrounding the plate (9), which carries the vessel (1), and is itself supported by the insulators (10). When a suitable electric current is passed through the electrodes, the sulphurous acid combines with the oxygen liberated by the electrolysis of the water, and the sulphuric acid formed becomes concentrated as the decomposition of the water proceeds. The hydrogen liberated is withdrawn through the tap (11), and the sulphuric acid by way of the tap (13).—O. R.

Hydrocyanic acid from waste gases; Extracting —. T. M. Percy and T. H. Byrom, Wigan. Eng. Pat. 1608, Jan. 23, 1908.

THE gases are passed through a coke tower or other suitable scrubber down which a very small quantity of water is allowed to trickle, the hydrocyanic acid thus being recovered in a comparatively concentrated form. The sulphur in the solution is then precipitated by a lead salt or by other suitable means, whereupon the hydrocyanic acid is distilled off and recovered. The process is stated to be especially adapted for waste gases from coking plants, recovering ammonium sulphate.—C. J. G.

[Bleaching liquors]; *Unstable chemically or electrically produced solutions; [Rendering stable —].* F. W. Alexander, Blackheath, J. C. McClelland, Merton, and F. M. T. Lange, London. Eng. Pat. 27,463, Dec. 12, 1907.

MAGNESIUM hydroxide, oxide, or carbonate, or preparations containing these substances are added during the process of manufacture in order to render unstable hypochlorite solutions, and more especially magnesium hypochlorite solutions stable. The solution is vigorously stirred during the process by means of an ebonite rod having one or more flaps of pure rubber, or alternatively the liquid may be beaten or shaken, or else allowed to percolate through the said magnesium compounds.—C. J. G.

Hydrosulphites; Manufacture of solid —. B. Willecox, London. From Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 20,198, Sept. 25, 1908.

HYDROSULPHITES are obtained in a crystalline condition by passing gaseous ammonia through their aqueous solution. The crystals are filtered off, with the aid of the pump, and suction is continued until they are obtained as a thick moist paste, in which condition they are quite stable.—A. S.

Barium carbonate; Manufacture of —. A. Caffin. Fr. Pat. 393,710, Aug. 27, 1908.

FINELY powdered barytes is digested under pressure with an excess of sodium carbonate solution in an autoclave. After the mixture has been maintained at the boiling point with thorough agitation for one hour, the clear liquor is decanted off, fresh sodium carbonate solution is added, and the process repeated until the barium sulphate has been entirely converted into carbonate.—O. R.

Barium chloride and carbonate; Manufacture of —. A. Caffin. Fr. Pat. 393,880, Sept. 2, 1908.

A MIXTURE of powdered barium sulphate, an alkali chloride, and coal is calcined, and the product lixiviated with hot or cold water and filtered. Barium chloride is obtained from the filtrate by crystallisation, or barium carbonate is precipitated in the solution either by means of carbon dioxide or of a solution of an alkali carbonate.—O. R.

THE perforated lead tube (2), is fixed inside the cylindrical, porous earthenware vessel (1), and surrounded by granulated coke, retort carbon, or silicic carbide. A rigid lead cover (5), and a porcelain bottom (4), close the top and

Barium nitrate and strontium nitrate; Process for the preparation of —. Traine und Hellmers. Ger. Pat. 205,167, Jan. 3, 1908.

Barium and strontium nitrates are prepared by heating the corresponding sulphides or hydrosulphides with calcium nitrate, preferably under pressure.—A. S.

Cryolite; Process for the preparation of artificial — from fluorspar. G. Loesekamm. Ger. Pat. 205,209, Nov. 20, 1907.

FLUORSPAR is roasted with potassium sulphate and charcoal, the product is lixiviated with water, and the solution, containing potassium fluoride, is treated in one of the following ways:—(1). It is mixed with sodium sulphate, and the precipitated sodium fluoride converted into sodium-aluminium fluoride by treatment with aluminium sulphate. (2). It is treated with aluminium sulphate, and the resulting potassium-aluminium fluoride treated with sodium sulphate. (3). It is treated directly with a solution containing sodium sulphate and aluminium sulphate.—A. S.

Potassium sulphide solution; Process for the preparation of —. J. A. Reich. Ger. Pat. 205,538, March 8, 1907.

THE requisite proportions of barium sulphide and potassium sulphate are finely ground together, and the mixture is introduced, in a thin stream, into boiling water, the boiling being continued, with or without application of pressure, until the reaction is complete. Air is excluded throughout the process.—A. S.

Silicon monoxide; Process of treating —. H. N. Potter, New Rochelle, N. Y., Assignor to G. Westinghouse, Pittsburgh, Pa. U.S. Pat. 908,131, Dec. 29, 1908.

FINELY-DIVIDED silicon monoxide is converted into the dioxide by burning it while suspended in an oxidising atmosphere.—F. SODX.

Liquefaction of gases and separation of air into commercial oxygen and nitrogen. G. A. Bobrick, Los Angeles, Cal. U.S. Pat. 908,644, Jan. 5, 1909.

THE gas (air) to be liquefied is first compressed and then after cooling is passed through a counter-current apparatus to the liquefier. The counter-current apparatus consists of a number of sections having outgoing and return pipes, the former being connected to separate expansion-chambers.—W. H. C.

Iodine; Extraction of — from seaweed. L. Boirault. Fr. Pat. 393,668, Oct. 31, 1907.

SEAWEED is arranged in the form of rings, and carbonised, the formation of ashes being prevented by occasional stirring. The charred mass is placed in wooden crates, which are introduced into a battery of lixiviators. A little calcium sulphate is added to the burnt weed, so as to convert the contained sodium carbonate and oxalate into the insoluble calcium compounds. Each lixiviating vessel consists of a cement vat provided with a double bottom, between the upper and the lower portion of which a steam pipe may be disposed to heat the solution. The concentrated lye is treated with a mixture of cupric and ferrous sulphates, in the proportion of 1 part of the former to 2 parts of the latter, and the precipitated cuprous iodide is filtered off and dried, after which it is introduced into porcelain retorts, and treated with sulphuric acid and ferric oxide. Iodine separates, and cupric and ferrous sulphates are regenerated for use in the next operation. The waste products of the process may be utilised as follows:—the extracted carbonised weed is dried and powdered; one-third of this mass serves to absorb the potassium salts contained in the waste liquor obtained from the whole mass, and after air-drying gives rise to a valuable manure. The remaining two-thirds of the charred weed is moulded into briquettes with lime and used as a fuel.—O. R.

Bromine containing chlorine; Process for purifying —. Deutsche Solvay-Werke, Act.-Ges. Ger. Pat. 205,448, Jan. 7, 1908.

CRUDE bromine is freed from chlorine by heating it carefully and very slowly to a temperature near to, but below

the boiling point of pure bromine. For instance the temperature is raised to 59° C. in the course of 36—40 hours. It is essential that the rise of temperature be very slow. It is stated that in this way samples of crude bromine containing 2.26 and 2.25 per cent. of chlorine were entirely freed from the latter with losses of only 6.3 and 3.5 per cent. respectively of bromine.—A. S.

Hydrogen peroxide; Process for the preparation of —. G. Teichner. Ger. Pat. 205,262, April 25, 1908.

IN the preparation of hydrogen peroxide by blowing superheated steam against a highly heated body (see Fischer, this J., 1908, 446; also Eng. Pat. 20,868 of 1907; this J., 1908, 123), there is a very large consumption of steam compared with the quantity of hydrogen peroxide obtained. According to the present patent, the steam leaving the heating zone is only partially condensed, and the uncondensed portion, carrying some of the hydrogen peroxide, is again passed over the heated body, these successive operations being repeated as often as is desired. It is stated that by condensing only one-tenth of the steam, 50 per cent. of the hydrogen peroxide present is recovered.—A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Standardisation of refractory materials. Times, Jan. 21, 1909. [T.R.]

A COMMITTEE has been formed of representatives of certain societies and manufacturers to consider ways and means for arranging the "grading" and standardising of refractory materials used in making furnaces, kilns, and ovens. At a conference held on Jan. 4th, the general opinion was that there was need for such a committee, and that the following preliminary scheme should be adopted:—(a) To arrange and classify the various refractory materials, clay, silicious, as silica and ganister; special, as magnesite, chromite, &c.; (b) To arrange standard specifications for the raw materials and for the manufactured products; (c) To consider the possibility of arranging for uniformity in certain "stock" or "standard" sizes; and (d) To arrange standard methods of testing, analysis, &c.

Each section will, at first, conduct its own part of the inquiry independently of the others, and prepare a draft of their suggestions to be submitted to the next meeting of the General Committee. These suggestions will be embodied in a provisional report to be sent back to the sections for approval or amendment, and finally published as the general report. It is proposed to revise this report periodically, to keep abreast of developments.

The sections which will conduct these independent inquiries will be industrial sections, the Ceramic Society section, and the manufacturers' section, and the scheme of procedure is as follows:—

Industrial sections include a chemical and electrical

section, a glass section, a metallurgical section (Iron and Steel Institute and Institute of Metals), a gas engineers' section, and a pottery section. The members of the committee representing the various industries should formulate the demands of their own industry. This will probably be best done by inviting opinions on the following lines:—(1) Materials at present in use, any general information as to analyses, &c.; (2) Conditions of use, nature of furnace operations, temperature, and whether the temperature is continuous or intermittent; (3) Criticism of materials at present in use; and (4) Suggestions as to improvement, both in material and in sizes and patterns available. The Ceramic Society section will deal with (1) the definition of refractoriness; (2) the grades of materials, based on (a) refractoriness; (b) class of material, aluminous, as clay and bauxite; siliceous, as ganister and silica; special, as magnesite, &c.; (3) the examination of raw materials, chemical analysis, standard methods, method of determining refractoriness, mechanical analysis, and behaviour at various temperatures, shrinkage, porosity, plasticity. The manufacturers' section will prepare suggestions as to elimination of odd and little used sizes and shapes, standard sizes and shapes, deviation from specified dimensions in special sizes, and as to the grading of clays as proposed by the English Ceramic Society.

Silicate melts. Greiner. See VII.

PATENTS.

Glass machine and process. E. L. Heintz, Coffeyville, Kans. U.S. Pat. 908,259, Dec. 29, 1908.

THE process consists in forming sheet glass by drawing a sheet from a molten mass of glass, supporting the sides of the sheet by applying guide rods to the extreme edges of the sheet, and heating these edges while allowing the body of the sheet to cool. The apparatus used consists of a crucible having openings in its bottom; a frame having depending side bars adapted to close these openings when lowered; rods secured to the lower ends of the bars and which can be drawn up through the openings when the frame is raised; and a bait between the rods.

—A. G. L.

Glass-furnaces. C. Royer. First Addition, dated Aug. 7, 1908, to Fr. Pat. 390,102, May 11, 1908 (this J., 1908, 1020).

A BAFFLE-PLATE is provided in the path of the flames, which keeps the latter longer in the neighbourhood of the central chimney, and so causes them to assume a higher temperature. The air used for combustion is also pre-heated to a greater extent than before, by causing it to traverse a second series of passages in the heated brick-work before it passes into the central shaft, whence it emerges to meet the gas in the furnace.—A. G. L.

Gas-kiln for firing and bending large plates of glass, firing china, and all kinds of enamels and ceramic ware; also applicable to other purposes. J. B. Payne, London. Eng. Pat. 27,501, Dec. 13, 1907.

A BRICK gas-kiln is provided with a bed-plate, consisting of an iron-tray, 3—4 in. in depth, filled with dry plaster of Paris. Angle-pieces provided with holes are attached to this bed-plate, the burners being attached to the angle-pieces, so that their upper ends always project one inch above the bed-plate. Between the bed-plate fitted with its angle-pieces and the walls of the kiln there is a clear space of $\frac{1}{2}$ in. The bed-plate is fixed on a carriage running on iron rails through one of the openings into the kiln; the bed-plate can be raised or lowered by means of worm gearing acting on four perpendicular screws fixed to the lower side of the bed-plate and worked by means of a handle fixed to the front of the carriage. The glass to be bent is placed on a mould of sheet-iron, which is placed on the bed-plate. Connection with the gas supply is made by flexible tubing. The bent glass is annealed in the same chamber after cutting off the gas-supply.

—A. G. L.

Ovens and kilns for drying or firing ceramic ware. A. Meakin, Ltd., and W. Jackson, Tunstall, Staffs. Eng. Pat. 26,189, Nov. 26, 1907.

THE patent refers to kilns fired with producer gas. The main gas flue is either carried round the outside of the kiln below the ground level, branches leading from this flue into each of the fire-mouths, or else it is taken directly to the middle of the kiln, below the ground level, and then made to enter a chamber out of which branch flues lead to the fire-mouths. The secondary air is admitted through flues passing under the bottom of the kiln radially toward the middle, and then returning to positions near the openings of the branch flues in the fire-mouths. The distinguishing feature is that the supply of gas and secondary air to each quarter of the kiln can be controlled, by dampers independently of a like supply to the other quarters.—H. H. S.

Ovens [for pottery]. Eng. Pat. 18,730. See I.

Kilns; Waste heat from —. Eng. Pat. 28,079. See I.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

The cement industry of the United States in 1908. E. C. Eckel. U.S. Geol. Survey. [T.R.]

ALTHOUGH detailed figures are not yet obtainable, an estimate based on the information available indicates that the production of Portland cement in the United States was somewhat less than forty million barrels. This compares as follows with the output of recent years:—1905, 35,246,812 barrels; 1906, 46,463,424 barrels; 1907, 48,785,390 barrels. The falling off from the 1907 output was heavy, and is particularly notable because it is the first decrease shown in any year by the American cement industry since its inception. The year 1909 opens with heavy stocks of cement on hand at most mills, but with good prospects for a steady, though slow, revival in the cement trade. It is unlikely that this revival will be sufficiently rapid to push mills to their capacity during the year. The total maximum capacity of existing plants is now about 60,000,000 barrels a year.

International Association for Testing Materials; Congress of —. See under X.

PATENTS.

Magnesia cement. C. Ellis, Larchmont, N.Y., Assignor to Ellis-Foster Co., N.J. U.S. Pat. 909,171, Jan. 12, 1909.

THE cement consists of a dry, substantially non-hygroscopic powder composed of magnesium oxide and saline substances, e.g., alkali chlorides and magnesium sulphate. The cement reacts with water to form a hard translucent material containing magnesium oxychloride. Zinc oxide may be added to the cement.—A. G. L.

Hydraulic cements, etc.; Art of making —. W. H. Harding, Philadelphia, Pa. U.S. Pats. 908,092—908,094, Dec. 29, 1908.

CALCAREOUS rock and "cement rock" (clay, etc.) are charged into a vertical kiln of the Rosendale type, with a layer of coal for each layer of rock. The quantity of fuel used, and the rate of combustion, are proportioned so as to effect the calcination of two-thirds to nine-tenths of the rock. The calcined materials are ground, thoroughly mixed and burnt to cement in a rotatory kiln. Or else, the preliminary calcination of the raw materials may be effected in separate kilns; or, finally, only the calcareous rock may be calcined, the clay, etc., being only ground and dried, but not calcined, before the cement materials are mixed.—A. G. L.

Sand; Process for consolidating and rendering water bearing — water-tight by means of a "milk" of cement injected under high pressure. Compagnie des Mines de Béthune. Fr. Pat. 393,814, Nov. 5, 1907.

BORINGS in strata of water-bearing sand are rendered water-tight by injecting a mixture of water and cement into the sand from a narrow tube furnished with openings at the end, from which the cement mixture is projected under high pressure by means of a pump.—A. G. L.

Plastic compositions (cements, etc.); Preparation of —. W. F. Lake, London. From H. S. Spackman Engineering Co., Philadelphia. Eng. Pat. 19,110, May 9, 1908. SEE Fr. Pat. 390,194 of 1908; this J., 1908, 1021.—T. F. B.

Kilns; Waste heat from —. Eng. Pat. 28,079. See I.

X.—METALS AND METALLURGY.

* *Steel; The structure of hardened —.* I. Formation and transformation of austenite. W. J. Kurbatow and M. M. Matwejew. Metallurgie, 1908, 5, 721–728.

THE authors propose to investigate the structure of hardened steel by a series of comparative papers which shall cover the ground. The present paper is a tentative attempt to examine the formation and transformations of austenite, which was chosen because its transformations can be carried out at a lower temperature and more gradually than is the case with the constituents of unhardened steel, and because it occurs in larger and better characterised crystals than do martensite, troostite, and sorbite, which also are present in hardened steel. To prepare austenite, Osmond's method was followed, on a small scale, steel containing 1.8–2.2 per cent. of carbon being heated to a temperature near its melting-point (1280° C.), and then quenched in mercury at not above 130° C. The authors summarise the conclusions at which they have arrived, partly from their own work, and partly from that of others, as follows:—The crystals of austenite are separated by needle-shaped crystals ("fers de lance") of troostite-sorbite, and by a network of troostite. On tempering, austenite probably changes into sorbite and troostite-sorbite, sorbite into pearlite. The old idea of transformation, austenite to martensite to troostite to sorbite to pearlite, the authors believe to be incorrect. The equilibrium, austenite \rightleftharpoons sorbite, changes from right to left at 90–150° C., and above 1000° C., and from left to right between 150° C. and 750° C., with a maximum at 250° C. There exist at least two compounds which are coloured by sodium picroate; on reheating, one changes more rapidly than the other into cementite or ferrite; if the transformation is rapid, the second compound changes into lamellated pearlite, if slow, into grains of pearlite. The first compound is to be regarded as troostite, the second as sorbite. Austenite itself is probably another carbide, of approximately the formula, $\text{Fe}_3\text{C}(\text{Fe}_3\text{C} \text{ to } \text{Fe}_{10}\text{C})$, which is stable above 1000° C., whilst the net-work of troostite is stable only below 250° C. Possibly, however, austenite is only a solution of carbon or carbide in γ -iron. Troostite and sorbite represent solutions of carbon in iron (α or β). Austenite heated to 65°–85° C. for 3 months suffers no change; even at 100° C. practically no transformation takes place; but at 118° C. a few days' heating suffices to produce noticeable effects. The transformations of steel proceed in distinct stages, and the same properties (capability of hardening, etc.) which render it valuable technically impede its investigation scientifically.

—A. G. L.

Manganese; Influence of — on the system, iron-carbon [steel]. F. Wüst. Metallurgie, 1909, 6, 3–14.

A NUMBER of iron-manganese-carbon mixtures were prepared: (1), by heating Swedish pig-iron containing 4.28 per cent. of carbon with manganese and sugar-charcoal in carbon crucibles in a "kryptol" electric

furnace, the melting points being observed; and (2), by heating the melts so obtained in magnesite crucibles in a Heraeus furnace at a temperature 10° C. above their melting-points for one hour. The magnesite crucibles were placed in iron tubes through which a stream of nitrogen was led, in order to protect the Marquardt-mass tubes of the furnace from destruction by the manganese, which volatilises appreciably even at the low temperatures used. It was found that addition of manganese regularly increased the quantity of carbon taken up, from 4.28 per cent. for the pig-iron containing 0.06 per cent. of manganese to 5.90 per cent. of carbon for a melt containing 80.45 per cent. of manganese. The melting-point dropped from 1132° C. for the pig-iron to 1124° C. for a melt containing 4.23 per cent. of manganese; from this point it remained almost constant until 13 per cent. of manganese was reached, after which the melting-point increased gradually to 1258° C. for a melt containing 80 per cent. of manganese. The influence of manganese on the pearlite arrest-point is more marked. Up to about 5 per cent. of manganese, each one per cent. added lowers this point about 20–25° C. on the cooling curve, and causes hysteresis (difference of the point as found on the heating and cooling curves) amounting to about 28° C. Beyond 5 per cent. of manganese the pearlite point disappears altogether. Manganese has little effect on the composition of the iron-carbon eutectic, 16 per cent. of manganese producing an eutectic with 4.05 per cent. of carbon or only 0.15 per cent. less than for the original pig-iron. This is contrary to Guillet's statement that 15 per cent. of manganese lowers the carbon content of the eutectic to 3.6 per cent. Manganese delays the separation of carbon as graphite, possibly because the iron-manganese carbides formed at high temperatures are more stable than the corresponding iron carbides; rapidly-cooled melts containing 50 per cent. of manganese approximated to the composition expressed by the formula, $(\text{Fe}, \text{Mn})_3\text{C}$. Microscopical examination of the melts confirmed the above results; the presence of manganese hinders the formation of pearlite, and favours that of troostite and of solid solutions. Melts with more than 5 per cent. of manganese contain no pearlite, and consist of a solid solution of carbides, martensite and cementite, in γ -iron.—A. G. L.

Gold extraction in Rhodesia. R. C. H. Cooke. J. Chem. Met. and Min. Soc., S. Africa, 1908, 9, 152–156.

THE ore at the Giant Mine in the Hartley district, a heavily mineralised chlorite schist, containing ironstone and quartz, is crushed and stamped, using 1250 lb. stamps and a $\frac{3}{4}$ to $\frac{1}{2}$ in. mesh screen. The duty per stamp reaches 15 tons per 24 hours, on account of the soft nature of the ore and the large apertures of the screens. The amalgamated plates, which are only 4 ft. long, retain 30 per cent. of the gold, the rest of the gold being "rusty" and not amenable to amalgamation. It is stated that the big tonnage and the coarseness of the pulp, does not injuriously affect the plates. After passing over amalgam traps, which collect about 400 oz. of amalgam per month, the pulp is de-watered in a "spitz" to a ratio of about one of water to one of sand, and the sands are crushed in a tube mill. The overflow from the de-watering "spitz" joins the discharge from the tube mill, and the whole is concentrated on the old type of blanket tables. These consist of a series of strips of material, 3 by $4\frac{1}{2}$ ft., resembling a military rug in texture, which are taken up and shaken in water, by hand, every half hour. The tailings coarser than 120-mesh are returned to the tube-mill for re-grinding. The concentrates, amounting to about 4 to 5 tons per day, and containing about 55 per cent. of the assay value of the ore, are re-concentrated on blanket tables to about a tenth. These final concentrates are rotated in amalgamation barrels with 300 c.c. of nitric acid for 4 hours, to clean the "rusty" gold; mercury is then added, and complete amalgamation attained in another four hours. Any gold remaining in the tailings is removed by passing the latter over an auxiliary blanket table and two sets of canvas tables, the final tailings running to waste, assaying under 1 dw. An extraction of nearly 88 per cent. of the total gold is attained, at a present cost of five shillings per ton. A diagram is given showing the arrangement of the plant.—F. R.

Gold-lead bullion; Cupellation of —. G. Melville. J. Chem. Met. and Min. Soc., S. Africa 1908, 9, 157—158.

A DETAILED description is given of the method of making the Mabor "tests" in use on the Crown Reef Mine, Transvaal. The "breast" of the "test" is composed of 60 lb. of new "mabor," a patent composition of magnesia, 30 lb. of Portland cement, and 30 lb. of crushed firebrick; the body consists of 150 lb. of used "mabor" assay cups, 75 lb. of cement, and 75 lb. of crushed firebrick. The materials are all ground to pass a 40-mesh (linear) sieve, and thoroughly mixed with 12 per cent. of water. The "tests" are tamped for $\frac{3}{4}$ hour, and then carved out and the litharge channels made. The life of these "tests" varies, but in one case, 15 cupellations were made and a total of 520 bars of 1000 oz. each cupelled in the one "test." A new "test" should not be used for 4 or 5 months, but, when required, it is fitted into an ordinary cupel furnace, two lead-gold bars are placed in it, and the temperature is very slowly raised. The lead-gold bullion is fed in, until the bath nearly reaches the litharge channel, the blast being then turned on, and when sufficient litharge is formed, the feed is continued until the litharge overflows. Three and a half 1000 oz. bars can be cupelled per hour. After all the lead-bullion has been fed in, the temperature is raised, and the "test" gradually tipped forward until all the lead is oxidised and blown off. The gold is then subjected to a higher temperature and a reduced blast, to eliminate as much of the remaining base metal as possible. The cupel "test" is finally lowered from the furnace and the gold removed.—F. R.

Detinning of tin-plate and its technical importance. K. Goldschmidt. Stahl u. Eisen, 1908, 28, 1919—1926.

IN the author's process of detinning (this J., 1907, 22) the scrap is packed tightly into baskets which are placed mechanically in closed vessels. The vessels are cooled and chlorine pumped in at a pressure of 4 atmospheres until the pressure remains constant, when chlorine and stannic chloride are removed from the vessels by suction. The residual iron is washed with water to remove the thin film of ferric chloride formed, which, if allowed to remain, causes rapid rusting of the iron. Lately, the demand for pure scrap-iron has led to the treatment of used tins, besides that of scrap proper. Before detinning, the tins must be carefully freed from moisture, organic matter, and solder (this J., 1907, 99). At present, about 75,000 tons of tin-plate are detinned yearly in Germany; in the rest of Europe about 25,000 tons and in the United States about 60,000 tons are dealt with per annum, yielding altogether 3000—3500 tons of tin yearly. The scrap-iron so obtained in Germany is approximately equal in quantity to that imported into that country.—A. G. L.

Ferrosilicon. G. W. Gray. Times Eng. Suppl., Jan. 27, 1909. (See also this J., 1904, 324. Also Dupré and Lloyd, this J., 1904, 622. Further see this J. 1906, 817; and 1909, 25.) [T.R.]

IN a letter on the dangers of ferrosilicon, the writer points out that only the 50 per cent. variety has, up to the present, caused trouble. Ferrosilicon made in the blast furnace and containing only a comparatively low percentage of silicon is quite safe to carry, as is the electrically made alloy containing up to, say, 40 per cent. of silicon, and also the alloy containing above, say, 60 per cent. of silicon up to 99 per cent., the only quality which need be looked upon with suspicion being that containing between, say, 40 and 60 per cent. of silicon, and even then only when it is made at certain works. This badly made alloy is dangerous to carry under any circumstances, and if packed, as has been suggested, in hermetically sealed iron drums, the danger of explosion would only be increased.

Bearing metals; The problem of —. S. K. Patteson. Electrochem. and Met. Ind., 1909, 7, 21—22.

THE increase of speed of modern heavy machinery has caused the subject of bearing metals to be one of great importance. The chief obstacle to the development of the turbine lies in the difficulty of securing proper bearing surfaces. Much of the bearing metal in use is sold under trade names, and little data is available as to the exact

composition of those alloys found most suitable for special requirements. Of all the commoner metals, lead has the greatest anti-frictional properties owing to the ease with which it "flows" under pressure, any inequality or damage of the surface of the bearing being rapidly equalised, thereby distributing the pressure over the largest surface and reducing the possibility of overheating. This property of readily flowing, however, prevents its use for heavy machinery as it cannot be retained in the recesses of the bearings, and a certain proportion of other material is necessary to give it stability. The following table gives approximately the percentage composition of the chief bearing metals on the market.

Alloys.	Lead.	Tin.	Anti-mony.	Copper.	Zinc.
Babbitt 1	80.0	20.0	—	—	—
Babbitt 2	72.0	21.0	7.0	—	—

					(Fe, 0.5)
					(Na, 1.3)
Tempered lead ..	98.5	0.08	0.11	—	—

The more lead a bearing metal contains the better are its anti-frictional qualities but also the softer and less resistant it is to compression. In order to combine strength with anti-frictional properties, bearings composed of iron or steel grids filled with a soft bearing metal have been tried.—F. R.

Magnesium-silicon alloys. R. Vogel. Z. anorg. Chem., 1909, 61, 46—53.

THE results of the thermal and microscopic study of the alloys indicates the existence of one compound, Mg_2Si , m.pt. $1102^\circ C$; this forms with silicon and with magnesium, eutectics melting at about 950° and $645^\circ C$, and containing 42 and 96 per cent. of magnesium respectively.—A. S.

Silicon; Alloys of — with tin, lead, and thallium. S. Tamaru. Z. anorg. Chem., 1909, 61, 40—45.

THE commercial silicon used contained 6.08 per cent. of iron and 1.74 per cent. of aluminium. Silicon and tin are miscible in all proportions in the liquid condition; no compounds are formed. Silicon is not miscible with lead or with thallium in the liquid condition.—A. S.

Cobalt and bismuth; Alloys of —. F. Duclleiz. Bull. Soc. Chim., 1909, 5, 61—62.

A STUDY of the alloys of cobalt and bismuth shows that these metals do not combine when heated together in an atmosphere of hydrogen, and that the liquid metals are only miscible within narrow limits. Prolonged heating of the alloys at $1400^\circ C$ results in complete elimination of the bismuth by volatilisation, pure cobalt remaining.—F. SONN.

International Association for Testing Materials; Congress of —. [T.R.]

THE fifth Congress of the International Association for Testing Materials will be held in Copenhagen in September, 1909. The principal questions to be discussed are divided under three heads:—

(a) Metals; (b) Cements; (c) Miscellaneous.

Among the more important problems are the following:—

(1) How to introduce international specifications for testing iron and steel.

(2) To establish methods for determining the uniformity of shipments of iron and steel, and to study how the ball-pressure tests can be used for piece-tests.

- (3) To establish uniform methods of testing cast iron.
- (4) To study the principles for specifications of copper.
- (6) The relation of chemical composition and weathering qualities in building stones; the action of smoke and sulphur dioxide on building stones; the weathering qualities of slates.
- (7) Rapid methods for determining the strength of cements.
- (8) Methods for determining the value of puzzuolanas for mortars.
- (9) Methods for determining the beginning and duration of the setting of cements.
- (10) The simplest method of separating the finest particles in Portland cement by liquid and air processes.
- (11) The behaviour of cements in sea water.
- (12) Accelerated tests of the constancy of volume of cements.
- (13) Influence of the proportion of water and sand on the strength of Roman and other cements.
- (14) Investigation of reinforced concrete.
- (15) Uniform tests of cements by prisms, and determination of a standard sand.
- (16) Method of testing the protective power of paints on metallic structures.
- (17) Uniform nomenclature of iron and steel.
- (18) Uniform definition and nomenclature of the bitumens.
- (19) Methods of testing caoutchouc.
- (20) Principles of specifications of oil for technical purposes.

Particulars may be obtained from the Iron and Steel Institute, Victoria Street, Westminster, S.W.; Prof. E. Marburg, American Society for Testing Materials, Philadelphia, Pa., U.S.A.; and Prof. W. H. Warren, University of Sydney, N.S.W.

Papers, which should not exceed eight octavo pages, should be sent in without delay to the General Secretary of the Association, Nordbahnstrasse 50, Wien II., Austria.

Mineral and metal production of the United States in 1908.

Eng. and Min. J., Jan. 9, 1909. [T.R.]

THE following table summarises the estimated production of the more important minerals and metals in the United States in 1908, so far as it has been possible to collect the statistics at so early a date. The figures for copper, lead, and spelter are based on reports received directly from the producers, who have communicated their actual output during the first 11 months of the year, together with their estimates of probable production in December; in many cases the estimates are for the last few days of December only. The other statistics are based chiefly on the reports of producers, State mine inspectors, and special correspondents:—

Uranium and euallium; Determination of —. Engle. See XXIII.

Determining copper. Hawley. See XXIII.

Antimony and tin; Gravimetric determination of —. Cohen and Morgan. See XXIII.

Silicate melts. Greiner. See VII.

PATENTS.

Metals; Coating of —. F. Plathner and V. Dorn, Berlin. Eng. Pat. 92, Jan. 1, 1908. Addition to Eng. Pat. 15,535 of 1906.

A MIXTURE, composed of powdered tin or lead, or some alloy having a lower melting point than lead, with a deoxidising substance and a neutral liquid, such as water or alcohol, is placed on the sheet of metal to be coated. Rolls, heated to a temperature sufficient to melt the metallic coating powder, are applied and a coating is produced and smoothed simultaneously. The rolls must be made of some material, such as aluminium, to which the coating does not adhere. Wire is coated by being electrically heated to a temperature above the melting point of the coating powder and then passing it rapidly through a bath of the coating mixture kept cool by suitable means. The wire is "finished" by passing it through a vessel packed with asbestos.—F. R.

Metals [zinc, etc.]; Process of coating with —. C. H. Zieme, Assignor to G. L. Patterson, W. R. Kinnear, and C. W. Johnson, New Castle, Pa. U.S. Pat. 909,274, Jan. 12, 1909.

A METAL is coated with a number of other metals (amongst which zinc predominates), by heating the metal after applying to its surface a slip consisting of a liquid mixed with 10 per cent. of a finely divided inert substance and 90 per cent. of a mixture of 95 per cent. of partially oxidised zinc with 5 per cent. of other metallic oxides.—A. G. L.

Zinc; Extraction of — from ores by the precipitation process. A. H. Imbert, Grand-Montrouge, France. Eng. Pat. 13,492, June 25, 1908.

BLENDE, or other ore, is fused with iron peroxide in a closed vessel, and cast iron, preferably molten, added. Heat is applied externally, care being taken to protect the mixture from contact with the air. The zinc is vaporised, and is collected in condensers, the iron being subsequently recovered from the residue. Oxidised zinc ores are first mixed with an equal weight of blende and then treated as described above.—F. R.

(a) Includes zinc-lead pigment.

Extraction apparatus [for ores or slimes]. C. M. Chamberlain, Pueblo, Colo. U.S. Pat. 899,512, Sept. 29, 1908.

THE apparatus, which is intended for the treatment of crushed ores or slimes, consists of a barrel containing a number of longitudinal filter-trays. The pulp is admitted through an upper inlet having an auxiliary inlet for the solvent liquid, water, etc., into a distributing chamber which communicates by separate inlets with the compartments formed by the filter-trays. The inlets are provided with seals to determine the depth to which each compartment shall be filled. The filtered liquid is discharged from the lower portion of each tray by means of branch pipes connected with a main outlet. The cakes on the filter-trays are loosened by forcing water upwards through the discharge pipes and then removed by detaching the discharge end and tilting the barrel.—O. F. H.

Matte or speiss; Art of separating metals from —. A. J. Wadhams, Riverton, N.J., and R. C. Stanley, New Brighton, N.Y., Assignors to Internat. Nickel Co., Bayonne, N.J. U.S. Pats. 900,452—900,454, Oct. 6, 1908.

ARSENICAL matte or speiss containing silver, nickel, cobalt, and iron is subjected to alternate reducing and oxidising roasts to remove most of the arsenic. The remaining arsenic is then removed by roasting with sodium nitrate and soda ash and dissolving out the sodium arsenate so formed. The residue is then treated with hydrochloric acid by which iron, nickel, and cobalt are dissolved, leaving most of the silver in the metallic state or as chloride. Iron is then removed from the solution by caustic lime, and silver together with any copper precipitated with hydrogen sulphide. Or, after roasting to remove most of the arsenic, the material is crushed and treated with boiling sulphuric acid of about 35° B., which dissolves a large proportion of the silver and some of the copper, nickel, and cobalt. The silver is deposited on copper and the solution neutralised with caustic soda and evaporated until nickel and cobalt sulphates crystallise out. The crystals are then calcined and the resulting oxides dissolved in hydrochloric acid, and the iron precipitated with lime, leaving a solution containing chlorides of copper, nickel, and cobalt, together with a small quantity of silver chloride which had escaped deposition on the copper.—O. F. H.

Chromiferous pig-iron; Process for manufacturing steel from —. F. D. Carney, Assignor to the Pennsylvania Steel Co., Steelton, Pa. U.S. Pat. 902,052, Oct. 27, 1908.

CHROMIFEROUS pig-iron containing 2—40 per cent. of chromium is blown preferably in an acid-lined converter, the temperature of the metal being kept as low as possible by charging scrap into the converter or by admitting steam with the blast. The blown metal, containing a small quantity of chromium, may then be recarburised and cast, or it may be transferred to a basic-lined open-hearth furnace where the remaining phosphorus and chromium are removed. The open-hearth furnace is charged previous to the addition of the molten metal from the converter with a small quantity of basic material and pig-iron in order to produce a "boil."—O. F. H.

[Iron] ores; Process of reducing —. G. L. Fogler, Pittsburg, Pa., Assignor to Fogler Heat and Reduction Co., Tacoma, Wash. U.S. Pat. 908,234, Dec. 29, 1908.

IRON ores containing silica are fused in a furnace under reduced pressure. The iron silicate so produced is treated in the same, or another furnace, with glass fluxes and a reducing agent, for the separation of the iron.—F. R.

Armour plates for ships, and other objects of steel or of steel alloys; Cementation process for making —. G. Ansaldo Armstrong and Co. Fr. Pat. 393,355, Aug. 10, 1908.

PLATES of mild steel are given a superficial layer rich in carbon by heating them in compressed carbonaceous gases. Thus, a highly carburized layer 8—9 mm. thick may be obtained by heating mild steel plates at 1100° C. for less than 12 hours in carbon monoxide gas under a pressure of 4

atmospheres. The plates may be surrounded with solid carbonaceous cementing material, and may afterwards be subjected to the usual thermal and mechanical treatment.—A. G. L.

Steel; Process of making an improved —. W. Sauntry Metals Co. Fr. Pat. 393,452, Aug. 18, 1908.

STEEL is heated somewhat above its critical temperature, and is quenched in a liquid capable of evolving chlorine. It is next heated slightly below its critical temperature, and quenched in the same liquid. It may be heated a third time, again to a point below its critical temperature, and quenched as before. It is claimed that a very even, fine-grained steel results, possessing increased tenacity and elasticity. The quenching liquid may be composed of 4.5 litres of water, 124 grms. of sodium chloride, 124 grms. of ammonium chloride, 10 c.c. of chlorine water ($\text{Cl} + 10\text{H}_2\text{O}$), 0.1 gm. of magnesium chloride, and 0.08 gm. of hippuric acid. Or, the hippuric acid may be replaced by uranium oxide, and hydrochloric and nitric acids added.—A. G. L.

Cast iron; Reducing the carbon content of —. R. Schiessl. Ger. Pat. 205,210, June 6, 1907.

THE cast iron is melted in a cupola furnace and sodium hydroxide is melted in an adjacent retort, and the two liquids are then allowed to flow, in regulated quantities, into a refining hearth. The alkali reacts with the carbon of the iron to form carbonate. The residual metal can be cast, the carbon left in it being in the form of pearlite.—A. S.

Metallurgical condenser, and method of condensing volatile metals. W. McA. Johnson, Hartford, Conn. U.S. Pats. 902,534 and 902,535, Oct. 27, 1908.

THE apparatus, which is intended more particularly for the condensation of zinc vapour, consists of a condensing chamber in which are a number of shallow horizontal troughs, at different levels, filled with molten zinc. As the zinc condenses, it overflows from trough to trough, thus giving a largely increased condensing surface, and is finally ladled out from the reservoir at the bottom of the condensing chamber. The troughs are supported on flues through which hot gases may be passed to regulate the temperature of the molten metal. The uppermost flues and troughs are provided with exterior basins guarded by seals, so that, if necessary, metal may be transferred to them from the reservoir in order to maintain a constant stream of molten metal from top to bottom of the condensing chamber. The metallic vapour is admitted at the upper end of the condensing chamber and the residual gases escape by an outlet at the bottom.—O. F. H.

Reduction-furnace [for the reduction of tungsten trioxide, etc.]. C. Van Brunt, Schenectady, N.Y., Assignor to General Electric Co., New York. U.S. Pat. 903,922, Nov. 17, 1908.

THE furnace consists of a number of horizontal combustion tubes, placed parallel to one another, the end of each tube being connected to the beginning of the next, by means of return pipes which serve as gas-drying chambers and contain a suitable drying agent; the ends of the combustion tubes are water cooled. A gas heater is situated at right angles to, and immediately below the tubes, and is slowly advanced along the length of the tubes simultaneously. The oxide to be reduced is placed in long "boats" in the tubes and hydrogen gas is circulated through the apparatus. Heat is then applied simultaneously to the ends of the tubes and gradually advanced as reduction proceeds, the water vapour produced being absorbed in the drying chambers.—F. R.

Furnace [; Metallurgical —]. J. P. McLimans, New York. U.S. Pat. 908,311, Dec. 29, 1908.

THE downcomer flue of a regenerative furnace for metallurgical and other purposes is terminated below by shoulders or projections, under which is run a car, adapted to receive flue-dust, etc. Shafts and cams are provided for raising the car into contact with the shoulders and so closing the flue and making a tight joint.—F. R.

Metals and alloys; Reduction process for producing — G. O. Seward and F. von Kugelgen, Holcombs Rock, Va., Assignors to Virginia Laboratory Co., New York. U.S. Pat. 908,154, Dec. 29, 1908.

METALLIC oxides, etc., are reduced and then alloyed by mixing them with a powdered brittle alloy, consisting of an alkaline-earth metal and some other metal, and "heating such mixture to ignition."—F. R.

Alloy [of platinum metals]. J. F. Clapp, Los Angeles, Cal. U.S. Pat. 909,283, Jan. 12, 1909.

THE alloy consists of iron (40–90 per cent.), iridium (1–30 per cent.), and platinum (0.2–14 per cent.), the percentage of iron being greater than that of iridium or platinum. Metals capable of facilitating solution of the iridium and platinum in molten iron may be added, e.g., molybdenum, or molybdenum, copper, and nickel.—A. G. L.

[Copper] ores; Process of reducing — J. Herman, Lincoln, Nebr. U.S. Pat. 909,795, Jan. 12, 1909.

METALLIC copper is produced by treating copper ores with hot reducing gases given off on burning carbonaceous fuel. The copper is extracted by means of a chloride solution, which is then electrolysed so as to yield metallic copper at the cathode and to regenerate the chloride solution at the anode.—A. G. L.
